By means of the Thompson resectoscope, 2 gm. of tissue was removed in multiple pieces from the anterior half of the neck between the 9 o'clock and 3 o'clock positions. No tissue was removed from the posterior lip, which was not incised. The pathologist reported the removed tissue to be inflammatory muscle. Postoperative drainage by means of a catheter was continued for 72 hours. After removal of the catheter, the patient was able to void quantities of urine ranging from 100 to 250 cc.; catheterization after voiding disclosed no residual urine, whereas the preoperative residual urine had measured 300 cc.

A program of general rehabilitation was then instituted, during which all osteoporosis of the bones disappeared and the renal and ureteral calculi disintegrated and were passed in multiple small fragments. Muscular strength gradually returned to the upper parts of the legs, and the patient was taught to walk, first with the use of crutches and later with glider canes, after many months of graduated effort.

Vesical function improved so that he could retain several hundred cubic centimeters of urine and had no incontinence. By this time ambulation had improved so much that he was discharged from the hospital to live in an apartment. He finally purchased an automobile, drove it to New York, and returned to Norway. He resumed his former occupation as manager of several stores and has since remained in good health. Final excretory urograms revealed normal renal function; no stones were visible in any portion of the urinary tract. Results of urinalysis and of urinary cultures were within normal limits.

COMMENT

Of greatest importance in the recovery of this patient was the physical therapy that was received over a period of many months. This was made possible, however, by correction of the disorder of the urinary tract, because prior to such correction repeated episodes of fever and chills had had the effect of so weakening and demoralizing the patient that he had almost lost all hope for recovery.

The degree of improvement just described is not unique. It has been observed in a large number of patients who have had the advantage of team therapy. Such patients have not been forced to put up with a poorly functioning bladder that retains a large quantity of infected urine. A bladder that cannot empty is an extremely inefficient reservoir for urine. Its capacity obviously is reduced not only by the imbalance of the muscles but by the infection that supervenes and makes it irritable. Many patients who have neurogenic vesical

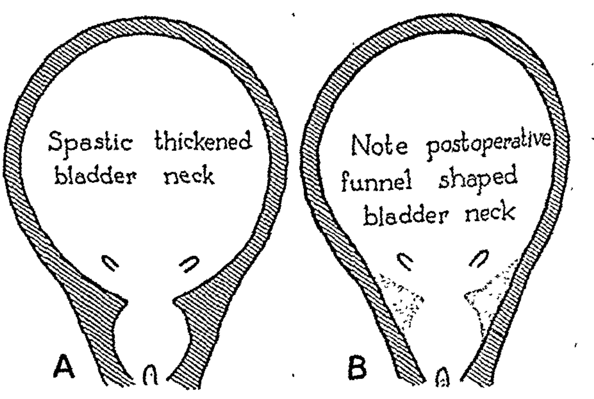

Fig. 3.—*A*, hypertrophy of the vesical musculature in cord bladder. *B*, funnel-shaped vesical neck resulting when the hypertrophied portion of the vesical neck (shaded part) is removed.

dysfunction experience repeated relapses of infection that are relieved by the intermittent use of an inlying catheter. Some ultimately are advised by their physicians to have permanent suprapubic cystostomy, which in my opinion should be used only in the treatment of patients who have paralyzed arms and cannot help themselves.

The use of transurethral resection of the vesical neck as a means of relieving any patient who has long-standing neurogenic vesical dysfunction should be seriously considered. The fear that incontinence might be increased by the operation has little basis in fact. The external sphincter is not disturbed if the operation is performed properly. Resection of tissue is confined to the vesical neck and prostatic region; the external sphincter is not cut or weakened in any way (fig. 3). I have questioned a number of urologists who have had extensive experience in transurethral operations; they agree that incontinence is corrected by transurethral procedures in the great majority of cases. There are a few patients whose vesical function is of the automatic type who will at times soil themselves if they do not watch the clock and correctly time the interval between urinations. As a rule, these are patients whose neurological defects are above the conus.

The results of transurethral resection are best in those patients whose original injuries occurred at or below the conus. Recovery of nerve function in many is relatively complete; some have only a defect in the sacral nerves, with resulting saddle anesthesia or minimal weakness of the muscles that control the feet. Transurethral resection has restored voluntary urination in many such patients who prior to operation could not void at all and had been forced to catheterize themselves regularly for periods ranging from many months to, in one case, 16 years.

It should be emphasized that many patients who sustain injuries to the spinal cord will spontaneously recover a satisfactory type of vesical function without the help of transurethral operations. In these patients, the bladder empties all but 1 or 2 fluid ounces (about 30 to 60 cc.); the urine remains entirely clear, or extremely rare episodes of cystitis may occur. These patients will do well and require, at most, only periodic chemotherapy to control the mild attacks of infection.

I wish to emphasize again that patients who have long-standing injuries to the spinal cord and who experience repeated attacks of infection of the urinary tract, who cannot void with a satisfactory, uninterrupted stream, with average effort, or who have a distressing incontinence, should be given the advantage of careful survey by a urologist who is skilled in transurethral procedures. Deformities of the vesical neck that can be corrected by transurethral resection will be found in a great percentage of such patients. The disability that these persons experience can be reduced appreciably or eliminated entirely by operation.

SUMMARY AND CONCLUSIONS

Cord bladders should be classified only on the basis of whether they are efficient or inefficient. An efficient cord bladder is one that the patient can empty or nearly empty. Long periods of continence are observed between urinations. Pyuria is absent or minimal. Stones do not form in the bladder or upper part of the urinary tract. Febrile attacks occur rarely if at all. An inefficient cord bladder is one that does not empty. As a rule, it retains 5 fluid ounces (about 150 cc.) or more of residual urine, which is usually infected. The patient is wet most of the time or has an extreme urgency type of incontinence. Stones are sometimes present, and febrile attacks occur frequently. Transurethral resection of the vesical neck can often convert an inefficient cord bladder into an efficient one.

CLINICAL MANAGEMENT OF URINARY RETENTION IN CHILDREN

Tracy O. Powell, M.D., Los Angeles

Pronounced urinary retention (megalobladder) in children is related in most cases to congenital lesions of the urogenital tract. The majority of these lesions are neuromuscular in origin. Effective treatment depends on accurate evaluation of the cause. Unless prompt and adequate urologic treatment is instituted, however, profound damage to the kidneys, with resultant shortening of the child's life, can ensue. This problem is encountered frequently in large pediatric clinics. The present study reviews the mechanics of urinary retention, describes a plan of examination that has proved useful in determining the type of retention in the particular case and its cause, and discusses treatment.

Although in many cases of pronounced urinary retention neurologic lesions may not be demonstrable, I am convinced the majority are of neurogenic origin. Etiological factors in neuromuscular dysfunction of the bladder in children include the following lesions:

Neuromuscular Lesions.—Neuromuscular lesions may be extrinsic to the musculature of bladder (including both upper and/or lower motor neuron lesions). Such lesions may be associated with cerebral palsy, cord bladder, spina bifida with meningocele, anomalies of the spine and sacrum, poliomyelitis, arachnoiditis, and tumors. Lesions intrinsic to the musculature of the bladder may be associated with Hirschsprung's disease, decreased numbers of ganglions (as demonstrated by neurohistological studies), and pseudovalves (indicating some type of nerve lesion).

Mechanical Obstructions.—Mechanical obstructions may be due to pinpoint meatus, urethral stricture, contracture of the vesical neck, ureterocele, giant verumontanum, or true valves, without infection. Severe infection in conjunction with any of these obstructions may produce atony of the bladder, which is often similar to that of neurogenic etiology. The etiologic factor of prime significance in the lesion with which this paper is concerned, megalobladder, is the intrinsic neuromuscular lesion. Incidentally, this vesical condition should not be

confused with cord bladder, the cause of which is related to lesions extrinsic to the vesical musculature.

Minor mechanical obstructive lesions, such as pinpoint meatus, urethral stricture, and even contracture of the vesical neck, are fairly easy to diagnose; they rarely produce the extreme variety of retention and vesical distention so hard to manage clinically. Correction or removal of such minor lesions generally will effect permanent relief. Transurethral resection of obstructive tissues about the vesical neck may be sufficient. When such lesser obstructions have caused urinary retention of long duration with pronounced infection, however, the clinical picture may resemble that of the more serious condition, megalobladder.

INTRINSIC NEUROGENIC LESIONS OF THE BLADDER

Swenson's [1] demonstration of a deficiency of ganglions in the trigone and near the ureteral orifices in megalobladder is especially significant. Whether or not his preliminary observations will be confirmed by studies in large groups remains to be learned. Certainly, clinical observations in patients with megalobladder indicate behavior similar to that in cases of urinary retention associated with Hirschsprung's disease in which there quite obviously is neuromuscular dysfunction of the bladder.

Pseudovalves.—In cases of megalobladder due to intrinsic neurogenic lesions of the bladder, it appears on cystographic and cystoscopic examination that the dome and the main portion of the detrussor lack stimuli arising from the trigonal level. The mechanism of voiding seems to be limited to the proximal portion of the bladder, without the cooperation of the dome; this, together with improper function of the internal sphincter, leads to flabbiness and infoldings of the bladder. These folds enter the neck and the posterior urethra, producing pseudovalves and thereby resulting in definite obstruction. The pressure from the abdominal musculature on the greatly distended bladder forces these folds further into th urethra, oftentimes dilating the posterior urethra in th male, causing depression in the posterior urethra and th neck of the bladder with relative elevation and engorg ment of the verumontanum and accentuation of i frenula (fig. 1). This infolding often is mistaken for true valve. The veru may become large enough to cor tribute to the obstruction.

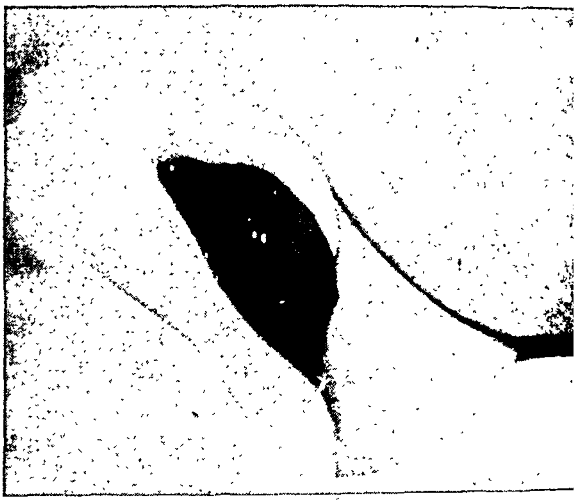

Fig. 2.—Photograph showing the trigone of the bladder, includi ureteral orifices and small ureterocele, being extruded through the urethı The patient was a 13-month-old infant with a large, flabby, atonic bladd

True valves are extremely rare and constitute a perm nent obstruction. Bell [2] has mentioned that in 32,3 postmortem examinations only 3 instances of a tr valve formation were found. In none of the 30 cases huge megalobladder and megaloureter did he find a evidence of valves or other obvious obstructions. In review of the pathological diagnoses in the leading ho pitals of Los Angeles, including the Los Angeles Gener Hospital, such valves were found to be extremely ra indeed.

The occurrence of pseudovalves as a clinical cond tion, however, is relatively common in my opinion. The importance as an obstructive urologic lesion needs en phasis. Pseudovalves may be observed clinically; hov ever, at autopsy such formations have been obliterate since the bladder has become fixed and usually ha assumed its normal contour as a result of being empt

Some of the patients with pseudovalve formatio observed on the clinic service at this hospital had prev ously been examined cystoscopically by competer urologists of wide experience and their lesions had bee diagnosed as true valves. In some of these cases, on oper ing of the posterior urethra retropubically, before an instrumentation could have obliterated the valves, larg folds entering the posterior urethra were found, wherea true valves could not be demonstrated.

Vesical Extrusion Through the Urethra.—In th female the musculature, as well as the mucosa, of th megalobladder may pass through the urethra and eve appear externally. In three cases a small ureterocele wa extruded through the urethra. This became increasingl distended with urine, giving rise to a mechanical tractio device that, on aggravation by the baby's crying and b the pressure of the abdominal musculature, forced ever sion of the bladder. Thus the entire trigone, ureteral orifices, and about half the bladder were pulled and pushed through the urethra to the outside (fig. 2). Without the ureterocele these bladders would not have remained on the outside but would have passed back through the urethra; in fact, the condition might have been missed as the obstructive cause for the urinary retention. Obviously such an extreme situation could not occur in the male.

PLAN OF EXAMINATION

Patients with intrinsic neurogenic lesions of the bladder observed in the past in many instances did not receive proper treatment owing to the inadequacy of examination. During the last five years my associate, Dr. H. H. Edelbrock, and I have developed a more thorough plan for examination that is offered as a guide to treatment.

Clinic and Office Routine.—The clinic and office routine includes a general survey, with a review of the history and physical examination. The urologic survey includes measurement of residual urine and capacity; determination of the type of infection; blood chemistry studies; intravenous urograms; and cystograms, cystometrograms, and occasionally sphincterometrograms. The neurosurgical consultation includes consideration of early surgical treatment in cases involving lesions such as meningocele and examination for disturbances of motor and sensory pathways. The neurourologic examination includes evaluation of dysfunction of the bladder accompanying lower or upper motor neuron lesions, with attention to the bulbocarvernosus reflex (S-2 and S-3), anal sphincter tone (S-2 and S-3), and anal reflex (S-5).

Hospital Routine.—In the hospital the study includes cystoscopy, retrograde pyelograms, and a barium enema. A pudendal block is performed, particularly in cases of vesical imbalance associated with upper motor neuron lesions.

CLINICAL OBSERVATIONS IN FIFTY CASES

More than 50 cases of megalobladder now have been studied. In every instance a large, flabby bladder obstructed the outlet and had produced changes due to back pressure, such as huge ureters and very severe hydronephrosis. To one not familiar with this type of case, it is almost unbelievable that children of 8 or 10 years could have renal pelves that hold 300 or 400 cc. each, ureters as large as the small bowel, and bladders that hold 1,000 to 1,200 cc. Yet in such cases an ample vesical outlet could often be demonstrated in that an adult cystoscope could be readily introduced through the urethra.

I am of the opinion that the obstructing mechanism is functional, being due to extrusion of folds of the vesical wall into the neck and the urethra. There appear to be all gradations of severity, from extreme cases to those in which there are minimal folds at the vesical neck that may or may not obliterate the outlet.

Although this discussion does not embrace cord bladder, some of the principles in management of that lesion have proved useful in cases in which folds at the vesical neck are minimal and detrussor function exists. If detrussor activity can be stimulated to produce pressures above the sphincter tone, a training program often will develop a satisfactory automatic bladder. Likewise in cases of flaccid vesical sphincter and atonic bladder, suprapubic massage with pressure (Credé) may produce a surprising degree of urinary continence. Dr. Ernest Bors [3] helped in formulating the plan of examination and his discussion of technique involved in these training procedures should be consulted. Following is a report of a case from our series in which this plan was used.

REPORT OF A CASE

Examination.—A boy, aged 3 years 8 months, was examined in December, 1947. The neurological history revealed that he had congenital hemisacrum with pes cavus of the left foot. There was a urologic history of urinary retention with chills and fever. The pain sensation was absent at the S-2 and S-3 levels on the left, and the touch sensation was diminished at the same levels. There was no Babinski reflex. The ankle jerk was absent on the left. The knee jerk was present bilaterally, and the cremasteric reflex was absent bilaterally. The bulbocavernosus reflex was positive, and the anal tone was good. Sphincterometry always revealed increased tone. Cystometry revealed that the bladder was initially atonic, then hypertonic after suprapubic resection. The tone was near normal at the last examination, after pudendal neurotripsy, with a few detrussor waves. Intravenous and retrograde pyelograms revealed bilateral pyelectasis and ureterectasis. Cystoscopy showed a bladder neck of the iris diaphragm type, with infolding of the vesical neck into the prostatic urethra. The barium enema revealed no abnormalities.

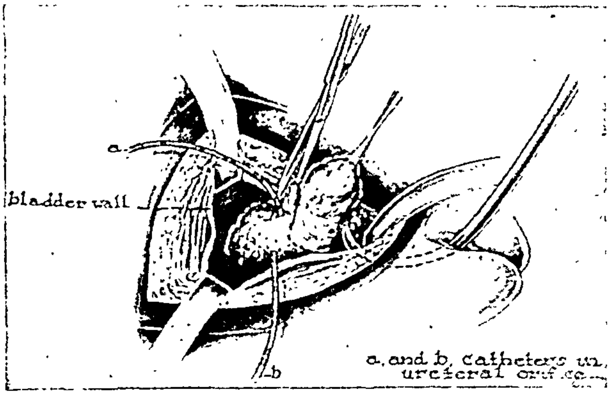

Fig. 3.—Redundant portion of trigone and bladder neck being resected in an infant.

Treatment by Open Resection.—In 1947 the child was incontinent and his bladder was distended. The capacity was 740 cc. There was 460 cc. of residual urine. In 1948, after the first resection, he was incontinent, with spasms of the bladder. The urine constantly showed evidence of infection. The capacity was 215 cc., with 170 cc. of residual urine. In 1950, after the second resection, he had the same symptoms. The capacity was 120 cc., with 90 cc. of residual urine.

Treatment by Pudendal Neurotripsy.—In 1951, before pudendal block, he strained to void. The bladder capacity was 120 cc., with 90 cc. of residual urine. After pudendal block, the patient voided easily. The capacity was 120 cc., with 2 cc., of residual urine. In 1951, after pudendal neurotripsy on the right side, his condition had improved. At the last examination he was continent, with a capacity of 320 cc. and only 15 cc. of residual urine.

When pudendal block was finally carried out in this child, the results indicated that pudendal neurotripsy probably would be of definite benefit. Accordingly, neurotripsy was done by Bors according to the technique of Huggins, Walker, and Noonan,[4] effecting complete elimination of obstruction and reducing residual capacity. Had pudendal block been done at the time of the initial examination, this child would have been spared almost four years of morbidity.

---

[3] Bors, E.; Comarr, A. E., and Moulton, S. H.: Role of Nerve Blocks in Management of Traumatic Cord Bladders, J. Urol. 63:653 (April) 1950.

Very few patients in this category, however, have come to our attention; usually in this type of case there are associated bony anomalies such as hemisacrum. In a number of instances good response to repeated pudendal block has been exhibited. A more lasting effect may be accomplished by repetition of the block, eliminating the necessity for neurotripsy.

SURGICAL TREATMENT

Minor vesical infoldings and contracture of the neck of the bladder, with but minimal damage to the upper urinary tract, may be amenable to transurethral resection. For more pronounced obstructive types of change, particularly the large, flabby bladders with huge irregular, distorted ureters and hydronephrosis, an effective plan of surgical treatment has been designed (fig. 1).

The bladder is approached through a transverse incision just over the pubic bone; the vesical neck and posterior urethra are opened as in retropubic prostatectomy. The large mucosal folds of the bladder are trimmed away, and the entire internal sphincter is enlarged by the electrosurgical loop. In some instances the amount of loose tissue in the region of the trigone is too great for resection with the electric loop but can be completely resected with knife and scissors and the cut edges resutured (fig. 3). In the majority of these patients the ureteral orifices are patent, and reflux is common; therefore, resection of the ureteral meatus is of little or no consequence. By use of male sounds corresponding in size to the enlarged ureters, patency of the ureters from the bladder to the renal pelves can be determined. If any degree of stricture is evident, dilation by manual manipulation of the ureter retroperitoneally over the dilating sound can be effected. An extremely long and tortuous ureter can be shortened by the "pull-through" operation. Completion of these procedures permits intubation of the enlarged ureters up into the renal pelves with no. 12 or no. 14 Levin tubes or, if preferred, polyethylene tubing. At the ureteral orifices the tubes are fastened by no. 0000 chromic surgical suture, brought out through small stab wounds on each side of the bladder, and thence brought through the incision. The superior half of the greatly enlarged bladder is resected, so that essentially a hemicystectomy is done. Often a few sutures are taken on each side of the bladder near the ureteral orifices to prevent the bladder from folding in at the neck. A Foley catheter of suitable size is left withir the urethra and entering the bladder but in boys neve is pulled into the fossa. Small pieces of absorbable gelatin sponge (Gelfoam) are placed around the urethr catheter in the open vesical neck. The catheter is pulle taut, but no tension is left on the catheter. Bleeding i completely controlled by electrocautery at the time o resection. The bladder is closed tightly in two layers A Penrose drain is left in the wound down to the bladde The fascia and muscles are closed in layers.

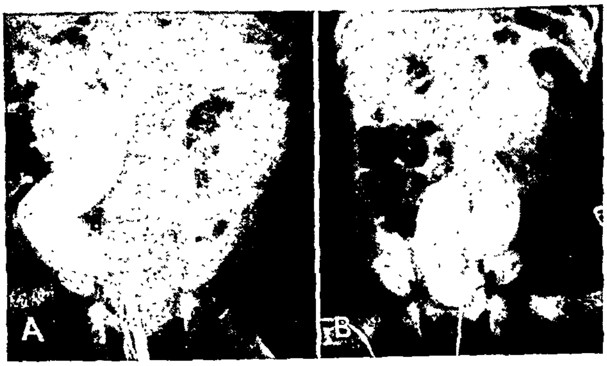

Fig. 4.—*A*, pyeloureterogram showing dilatation of the upper urinary tract on the right side in an infant of 2½ months. *B*, pyeloureterogram showing more pronounced dilatation of the upper urinary tract on the left side in the same infant.

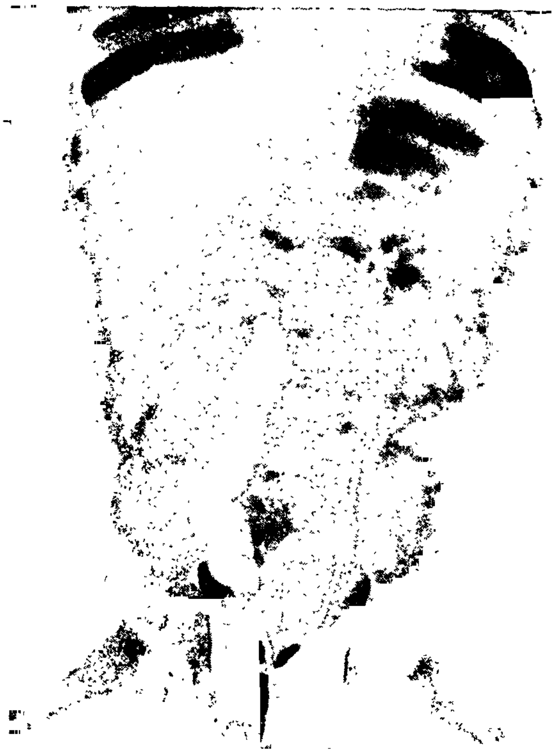

Fig. 5.—Bilateral pyeloureterogram in the infant shown in figure 4, year following the operation, except that the right ureter was used as control and was not intubated. Note the remarkable improvemen particularly of the left ureter and pelvis.

Minimal irrigation is permitted, and only sterile isotonic sodium chloride solution is used. The tubes withi the ureters are left in place for two to six weeks, and irrigation is limited to an amount necessary to assure thei being kept open. When there are advanced pathologica changes in the upper urinary tract, if the splinting tube have been properly placed and their positions maintained, it is advisable (convenience and expense permitting) to prolong the period of ureteral intubation. Regeneration of the kidneys in young babies following relief from pronounced obstruction can be remarkable (fig. 4 and 5). Such profound changes as illustrated obviously would not be expected in older children in whom infections have become chronic and extensive fibrosis exists. This one combined operation makes possible elimination of multiple individual surgical procedures such as nephrostomy, ureterostomy, ureteroplasty, permanent cystostomy, transurethral resection, and use of permanent catheters.

---

[4] Huggins, C.; Walker, A. E., and Noonan, W. J.: Sympathetic and Pudendal Neurectomy for Vesical Atony, J. Urol. 41: 696, (May) 1939.

SUMMARY AND CONCLUSIONS

In infants and children with retention of urine it is imperative that immediate drainage be instituted to avoid damage to the kidneys. Drainage should be maintained until a complete examination has been carried out and treatment of the essential lesion is under way. In most instances a retention catheter is necessary.

The majority of such patients suffer from congenital neurogenic anomalies of the vesical musculature. When the bladder is large and flabby, vesical folds may obstruct the neck, producing changes in the upper urinary tract due to back pressure. This clinical entity as referred to here is termed megalobladder for lack of a better term, and is to be distinguished from cord bladder. In some instances these folds extend into the urethra and may be mistaken cystoscopically for true valves. The frequent occurrence of such obstructive folds, referred to as pseudovalves, and the rare existence of true valves are emphasized. In girls the vesical folds may extrude through the urethra; if ureterocele exists, the bladder as well as the lower ends of the ureters may be extruded.

A plan for examination is presented that facilitated diagnosis and permitted more specific choice of treatment in 50 cases of pronounced urinary retention in children. In a few cases pudendal block and pudendal neurotripsy were of diagnostic and/or curative value; in the majority surgical treatment was necessary.

The aim of surgery is to promote urinary compensation as quickly as possible. Transurethral resection of vesical folds (pseudovalves) was effective in minor degrees of obstruction. An operation combining resection of excess tissue at the neck, manipulation and/or shortening of ureters, ureteral intubation and resection of the superior portion of the bladder—in some instances, hemicystectomy—was useful. *It permitted elimination of multiple* individual surgical procedures, an important consideration in view of the advanced pathological changes in these critically ill children.

Careful management postoperatively, regardless of the type of surgical treatment, is of extreme importance. Adequate drainage must be maintained until the urinary tract can become compensated. It may be necessary to retain the catheter, suprapubic cystostomy, or nephrostomy for months or years.

ANATOMY AND NERVE SUPPLY OF URINARY BLADDER

R. E. Van Duzen, M.D.
and
C. G. Duncan, M.D., Dallas, Texas

The anatomists have described the human urinary bladder as a pear-shaped structure made up of an external longitudinal layer of muscle fibers, a middle circular, and an inner longitudinal layer extending from the ureteral orifices down into the urethra. These fibers can be traced to the area about the verumontanum in the male bladder and to the vicinity of the external sphincter in the female. This layer of muscle fibers is easily dissected free from the underlying muscle fibers and is usually called the trigone. We have found the two remaining layers not to be distinct but to consist of freely interlacing muscle fibers, and we prefer to designate them as the detrusor muscle of the bladder.

Scher[1] has recently described "right and left lateral muscle bands which are more distinct and separate than the trigone muscle." These bands are described as originating in the posterior wall of the bladder and passing over the lateral wall of the bladder and the internal vesical orifice, through the prostatic urethra in the male and deep urethra of the female, to the region of the external sphincter. We have noted condensation of fibers that suggests what Scher has described; however, we have always found that the fibers are not a distinct structure but interlace with other fibers. They are not a separate structure comparable to the trigone muscle.

ANATOMY AND EMBRYOLOGY

The urinary bladder is primarily a hindgut derivative, as are the posterior urethra in the female and the prostatic urethra in the male. The exception is the trigone muscle, which is of wolffian duct derivation. The nerve supply of the bladder and posterior urethra is chiefly of sacral origin. The trigone is the exception, deriving its innervation from the hypogastric, or sympathetic, nerves. At the urologic seminar of the south central branch of the American Urological Society recently, Patton stated he found the bladder wall continuous with the prostate and without a fibrous separation. He stated he would not expect a fibrous septum, because fibrous tissue implied stress. He stated that, when muscle fibers in vitro were subjected to pull or stress, fibroblasts were promptly layed down.

We have previously described the prostate as the glandular portion of the bladder neck. We pointed out in 1944[2] that, in 4th to 7th month embryos, the glands in the bladder neck are nearly as numerous and well developed in the female as in the male. After the 7th month, there is a regression of the glands in the female. The fibrous septums, which have been interpreted as septums between lobes of the prostate, are fibrous bands resulting from contractions of the trigone in opening the internal vesical orifice during urination.

From the Southwestern Medical School of the University of Texas (Dr. Duncan).

Read in the Symposium on the Neurogenic Bladder before the Section on Urology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

[1] Scher, S.: Some Observations on Anatomy of Bladder Neck and Posterior Urethra with Reference to Prostatic Observation, Brit. J. Urol. 22: 116-124 (June) 1950.

[2] Van Duzen, R. E.: The Glands of the Female Urethra, Urol. & Cutan. Rev. 48: 363-364 (Aug.) 1944.

As we pointed out earlier in this paper, the detrusor muscle and the prostatic urethra are innervated by the parasympathetic or sacral nerves, the nervi erigentes, arising from the sacral segments 2, 3, and 4 of the spinal cord. The trigone, having been derived from the wolffian duct, receives its nerve supply from the hypogastric, or sympathetic, nerves, which have arisen from a higher segment of the embryo.

The center in the brain for urination is located in the preoptic region of the hypothalamus. Stimulation of this region results in the contraction of the bladder wall and emptying of the bladder. It is believed that a pathway leads backward from this center through the hypothalamus and finally passes, perhaps, in the ventrolateral white column of the cord to end on cells in the gray column at the level of S 2, S 3 and S 4. The main group of fibers seem to end on S 3, as they apparently constitute the greater portion of the fibers forming the pelvic splanchnic nerve, or the nervi erigentes. It is well to state, however, that the exact pathway through the brain stem and cord has not been definitely established at this time.

We believe much of the confusion about the act of urination woud cease if it was recognized that the muscular wall of the bladder and the posterior urethra in the female, and the prostatic urethra in the male, is a continuous structure.

THE ACT OF URINATION

Young[3] first suggested in 1918 that the trigone helped to open the internal vesical orifice. He stated: "This brings up the question of the part taken by the trigone in the act of urination. It seems to me to indicate that one function of the trigone is to pull open the interior sphincter of the bladder. I have long held to this view, as I have frequently observed, during cystoscopy, that if violent desire to urinate came on, the trigone would contract greatly and the prostatic orifice would open widely. The median, posterior portion being apparently drawn backward by the muscle fibers which run from the trigone down in the posterior urethra, and which were seen to contract violently. The opening of the internal sphincter during urination will have to be viewed, therefore, not as an inhibitory action, as heretofore, but as the result of the contraction of the powerful trigonal muscle, which passes in the form of an arc through a weaker muscle of circular shape (the vesical sphincter) and pulls it open when it contracts."

In a previous paper,[4] one of us (R. Van D.) has described his conception of the act of urination. It is an elaboration of that advanced by Young and his coworkers, Wesson,[5] and Macht.[6] According to this theory, the phases of urination are as follows. 1. The first act of urination is the contraction of the trigone. This depresses the posterior lip of the internal vesical orifice. 2. The next stage is a wave of contraction in the detrussor muscle, starting in the region of the internal vesical orifice and extending backward toward the dome of the bladder. This contraction wave, as we have previously pointed out, causes a lateral pull on the internal vesical orifice, further opening it. This should be remembered because the trigone is supplied by the sympathetic nerves and the detrusor muscle by the parasympathetic, or sacral, nerves. If the trigone is paralyzed by section of the sympathetic nerves or by drugs, the first act of urination, that is, the depression of the posterior lip of the internal vesical orifice, is omitted. The detrusor muscle must open the internal vesical orifice by lateral pull on the circular fibers about the internal vesical orifice and by increasing intravesicular pressure. In such cases we see hypertrophy of the detrusor muscle fibers, indicating it is not so effective as the normal mechanism. When the detrusor muscle is paralyzed, there is no tonicity of the bladder and there is no expulsive force; hence there is complete retention. Later the intrinsic nerve control manifests itself and the bladder tonicity returns to some extent. 3. The last phase of urination consists of contraction of the abdominal muscle and increase in the intra-abdominal pressure. In contrast to these conditions, there may be hypertonicity of either muscle. By the combination of an abnormal physiological state of one muscle with a normal or abnormal state of the other, various conditions are produced, giving a diverse chain of symptoms. Only by determining which muscle or what nerves are affected is rational treatment possible. There has been considerable discussion as to whether there are dilator fibers in the bladder. We recently saw a patient who did not empty his bladder when the cystoscope sheath was in the bladder. Pressure was applied over the suprapubic region and about 400 cc. of urine was expelled. On release of the suprapubic pressure, air was heard to pass into the bladder. A roentgenogram showed a bladder filled with air. This would be interpreted by many to demonstrate dilator fibers. However, this has been relieved by giving methacholine chloride. What was the cause of the negative pressure in the bladder? We feel it is due only to negative intra-abdominal pressure with a weak detrusor muscle.

In 1936 one of us (R. Van D.), with Looney,[7] pointed out that, if during cystoscopy the lateral walls of the internal vesical orifice were observed when the patient strained to void, the walls were often seen to fall away, just as contraction of the trigone depresses the floor of the internal vesical orifice. We further noted that this continued after the trigone was paralyzed by section of the presacral nerve. Scher many years later described a like observation but believes it is produced by contraction of distinct lateral muscle bands. We question only the existence of separate muscle bands.

Young in his discussion of the 1937 paper[7] states: "Dr. Van Duzen's demonstration of the part played by the lateral detrusor muscles in holding open the vesical orifice is an interesting finding, and confirms our view that the act of micturition is from first to last an active process, being initiated by the trigone which holds the neck open with the assistance of the lateral muscles, which also take part in expelling the urine with the other detrusors."

INNERVATION

The reports by Learmonth [8] that stimulation of the presacral nerve would contract the internal sphincter and that section of the nerve would produce relaxation of the internal vesical orifice has produced most of the confusion about the act of urination. In 1932 one of us (R. Van D.) published our observations on the cystoscopic findings after presacral neurectomy.[9] We pointed out that the trigone was paralyzed and that there was no relaxation of the internal sphincter. We further pointed out that these patients noticed a delay in initiating the act of urination and a need to strain. We also reported this was often relieved by the use of epinephrine, a sympathetic stimulant. In discussion of this observation it was suggested that we had not completely cut all the presacral nerves. Subsequent observation by others has shown that the sympathetic nerve has no effect on contracting the internal vesical orifice. We have observed the effect of stimulation of both the hypogastric or presacral nerves and the sacral nerves in the Rhesus monkey. There is ttle if any change when the hypogastric nerve is stimlated. If the anterior branch of the second sacral nerve s stimulated as it emerges from the sacral foramen, a vave of contraction is seen to start at the neck of the ladder, proceeding upward toward the apex, causing he bladder to elongate and rise toward the anterior wall. This is followed by a wave that passes downward, shortening the bladder, and causing evacuation. This is similar o Muellner's fluoroscopic observations in man. Heimburger, Freeman, and Wilde [10] found that the anterior root of S 3 is the dominant nerve supply in man but that S 2 and S 4 are of less importance.

CONCLUSIONS

The bladder wall consists of two groups of muscle fibers: *the trigone muscle and the detrusor muscle.* The trigone, innervated by the sympathetic, or hypogastric, nerve, starts the act of urination by depressing the posterior lip of the internal vesical orifice. The detrusor muscle, innervated by the parasympathetic or sacral nerves produces lateral pull on the fibers about the vesicle neck, thereby further opening the outlet, and, by a contracting wave, expel the contents of the bladder.

The muscular structure of the prostate is a continuation of the fibers of the detrusor muscle of the bladder. There is no fibrous septum between bladder and prostate. The so-called capsule of the prostate is a compression layer resulting from hypertrophy of the prostatic glands. Fibrous septums indicate stress. The septums that have been said to divide the prostatic urethra into lobes are the result of repeated contractions of the trigone.

Sectioning of the hypogastric or sympathetic nerve causes paralysis of the trigone. It does not produce relaxation of the internal vesical orifice. Sectioning of the sacral or parasympathetic nerves produces relaxation of the internal vesical orifice and paralysis of the detrusor muscle of the bladder.

RADICAL PROSTATECTOMY FOR CANCER

John K. Lattimer, M.D., Archie L. Dean, M.D., Ralph Veenema, M.D.
and
Edward Rafferty, M.D., New York

Carcinoma of the prostate gland ranks a close third among the leading causes of deaths due to cancer in males. Radical prostatectomy for the early localized tumor is the only known method of curing patients with this disease. While all prostatic cancers are curable by surgery for a certain length of time after they first develop, they produce no symptoms during this operable stage. As a result, only a pitifully small proportion of these cancers are discovered and referred to the surgeon early enough to be cured by radical prostatectomy. The great majority (approximately 95%) are inoperable when first discovered, and the patients continue downhill to die in one to five years, despite the palliation provided by orchiectomy, estrogens,[1] or cortisone. The results from bilateral adrenalectomy have been disappointing, and it may soon be abandoned as a treatment for carcinoma of the prostate.

Radioactive isotopes, such as gold 198 and phosphorus 32, which are now being investigated, appear to have a purely local action, at least in their present form, and thus may not be curative. For patients over 70 years of age, palliation for one to five years by hormone therapy may appear to be an acceptable duration of salvage (except to the patients and their families), but such a period of palliation for men of 55 years is definitely unsatisfactory. The purpose of this paper is to restate the plea for periodic rectal examinations of all men over 50 years of age, so that early cancers of the prostate will be detected in time, and to present some helpful refinements of the retropubic technique for radical prostatectomy.

The one person who can save men with cancer of the prostate gland is the physician who does annual physical examinations. He alone has the opportunity to detect the nodules or alterations in density that usually originate, fortunately, in a position where they can be easily pal-

pated on rectal examination. These suspicious areas can be biopsied with a needle, punch, or scalpel. All three methods have been recommended by experienced urologists.

It is encouraging to observe that a number of the largest automotive and industrial organizations have followed the example of the U. S. Army and have adopted a policy of routine physical examinations for their executives, realizing that many disorders, like prostate cancer, must be detected early, before symptoms develop. Once symptoms of urinary obstruction occur or the serum acid phosphatase level rises, it is usually too late for curative surgery. The recent report of Col. Joseph Kimbrough [2] shows how valuable routine examinations can be in the early discovery of prostatic carcinomas, while curative surgery can still be used.

DIAGNOSIS OF EARLY LESIONS

Palpation by rectum with the finger may reveal a nodule in one lobe of the prostate gland or abnormal firmness of one lobe as compared to the other. Either of these findings is sufficient to require a biopsy and an assay of the serum acid phosphatase. Also, if one side of the prostate gland is larger than the other, carcinoma should be suspected. Asymmetry can be caused by a prostatic abscess, but bogginess, fever, and pain are common accompaniments that are not usually present with cancer. The somewhat rare prostatic infarct may not be distinguishable from a cancer by palpation alone. Reliance on palpation alone leads to too-frequent diagnosis of carcinoma, since some cases with nodular benign hypertrophy, calculi, or tuberculosis can resemble cancer, as demonstrated by Goodwin.[3] Several supplementary diagnostic aids, such as roentgenograms, biopsies, phosphatase studies, and endoscopy, are available, however, to verify the clinical impression of carcinoma.

Palpation by rectum is important in determining whether the carcinoma is operable. Fixation, extension beyond the seminal vesicles, or induration of the periprostatic tissues suggest inoperability, but they are sometimes difficult to detect, and surgical exploration may be necessary to determine whether the growth is removable. Massive, fixed glands are definitely inoperable and amenable only to palliative treatment.

Acid phosphatase assays of the serum are of diagnostic value only when the serum level is elevated. Prostatic carcinomas that have not broken through the capsule cause no elevation of the serum acid phosphatase level, and a large proportion of carcinomas that have broken through the prostatic capsule and have metastasized still cause no elevation of the serum acid phosphatase level. When this level is elevated above 3 Gutman units per 100 cc. or 1 Bodansky unit, however, it does indicate that prostatic cancer has broken through the capsule and is no longer amenable to radical prostatectomy. Whether cures are likely to follow the shrinking of these cancers with estrogen treatment and the removal of them by radical prostatectomy has not yet been determined, although patients so treated may not subsequently suffer from obstruction of the bladder outlet.[4]

Cytological (Papanicolaou and Traut) studies of exfoliated cells in expressed prostatic secretions appear to be of little practical value in patients with small (operable) prostatic cancers, perhaps because the carcinomatous nodules lie in the periphery of the gland.[5]

BIOPSY OF THE EARLY LESION

Normal results from biopsy of a firm or nodular gland are always of doubtful value. Open perineal biopsy, even though a sizable wedge of prostatic tissue is removed, is by no means infallible. Frozen sections of tissue taken from the prostate during perineal exposure are often difficult to interpret accurately, especially if the pathologist is able to study only two or three such specimens a year. It has also been noted that the nodule that was palpated in rectal examination is sometimes difficult to locate when the gland is exposed. It also has been noted that occasionally the nodular area will yield a normal biopsy specimen whereas other areas of the prostate that felt quite normal to the palpating finger will yield carcinoma. If the frozen sections are inconclusive, Goodwin [6] and others close the perineal incision and wait for study of the permanent sections. Reoperation for radical perineal prostatectomy is not difficult if it is done within seven days after the surgical biopsy, but cutting into any cancer reduces the chances of curative surgery.

Needle biopsy or punch biopsy is much easier to do, although accuracy in hitting the affected area depends on the experience of the examiner.[7] This method has the advantage that the removed tissue can be studied on permanent sections rather than on frozen sections. Multiple specimens can be taken, and repeat biopsies are possible if doubt persists. The likelihood of producing implants of carcinoma cells in the tract of the needle biopsy has been discussed, but no cases of such implantation have been reported. Such a danger exists theoretically with every type of biopsy, but, at present, there does not appear to be any safer substitute, and spread of prostatic disease as the result of biopsies has never been demonstrated.

SURGICAL TECHNIQUES

The retropubic (or suprapubic) technique for radical prostatectomy has been gaining favor among many surgeons (Flocks,[8] Memmelaar,[9] Chute,[10] Stockwell,[11] and Millin [12]) for several reasons. 1. The region of the external sphincter is not disturbed, so that the incidence of incontinence is low following the procedure. 2. The extent of lymph node involvement can be estimated at the outset of the operation. 3. The fascia surrounding the seminal vesicles can be easily and completely dissected out, under vision, by the retropubic technique. This fascia is even more important as a site for early metastases than the seminal vesicles themselves, according to Jewett.[13] He found no carcinoma cells in the lumen of the vasa or vesicles in 78 specimens examined, while he frequently found cancer cells in the perivesicle fascia. Jewett reports a 50% five year survival among the patients who were operated on and in whom the rectal examination showed no evidence of extension of the tumor.

The perineal technique for radical prostatectomy is satisfactory in the hands of those who have had long training in its use. This approach has never become popular, however, despite 50 years of teaching by its advocates. It is perhaps understandable that surgeons who only occasionally perform a radical prostatectomy might prefer the more familiar suprapubic (or retropubic) route. For this reason, we attempt to describe some of the technical points that make the retropubic radical operation easier for us.

RADICAL RETROPUBIC PROSTATECTOMY

Obesity of the patient, to our surprise, has not interfered seriously with the retropubic approach. A deep, obese perineum can sometimes be more of a handicap to the operator than an obese abdomen. Proper position of the patient is important. An extra pad is placed over the kidney bridge, and the patient is placed so that his sacrum is directly over the kidney bridge. This bridge is then raised 6 in. (15.2 cm.), so that the pelvis is greatly hyperextended. In this hyperextended position, the floor of the pelvis and the cut end of the urethra are much more accessible. A slight degree of Trendelenburg is desirable so that the peritoneal contents will fall "upward" out of the way. A stiff rubber 24 F. catheter is inserted into the urethra, and the bladder is drained. The catheter is then sutured to the prepuce with silk sutures, so that it cannot slide out of the urethra while the palpating finger is seeking the plane of cleavage between the urethra and rectum. A midline suprapubic incision is made, which need not extend above the umbilicus in most cases. The Cherney incision is well adapted for this exposure but is not usually necessary. A self-retaining retractor is inserted to hold the rectus muscles widely apart, and an assistant is assigned the duty of keeping the bladder and peritoneum pushed upward, away from the field. Any sizable veins in the retropubic space are then ligated and divided. The puboprostatic ligaments on each side are palpated and cut close to the prostate. In this way, any branches of the dorsal vein of the penis, which might accompany these ligaments, may be grasped and tied. It is our practice to ligate these bleeding points rather than to fulgurate them. Our reason for cutting the puboprostatic ligaments close to the prostate is a part of a plan to leave the tissues in the vicinity of the external sphincter undisturbed. The finger then is passed under the apex of the prostate and under the membranous urethra. The stiff 24 F. catheter that was sutured into the urethra earlier can now be easily felt within the urethra.

Perforation of the rectal wall can occur at this stage of the operation, and to prevent this the surgeon may insert his left index finger into the rectum while he separates the urethra from the rectum (fig. 1). This will enable the surgeon with his dissecting right index finger to easily identify the rectal wall as distinguished from the wall of the urethra, which contains the catheter. As soon as this plane of cleavage is established, another catheter or a rubber tissue drain can be passed under the membranous urethra. The urethra is partly cut across at the apex of the prostate. When the inlying catheter is exposed, in our practice, two marking sutures of heavy (no. 0) chromic absorbable suture are inserted into the distal stump of the urethra at its ventral border. Any finer sutures might soften and break before the end of the operation. It is perfectly practical to place one such suture on either side of the midline to insure a good "bite" in the urethral wall before it is completely divided. As soon as the urethra is divided, the stump retracts distally and is thereafter more difficult to reach for the purpose of introducing new sutures. After these marking sutures are inserted and the urethra is transected, the apex of the prostate gland is lifted up with a vulsellum tenaculum. The rectal wall is then wiped away from the under surface of the prostate and seminal vesicles. With the upward pull on the prostate gland, the seminal vesicles and their surrounding fascia are placed under tension and can be felt running downward laterally, astride the rectum, at the upper limits of the prostate. With a sponge stick, the vesicles with their fascia can be separated from the surrounding tissues so that they stand out like cords under tension.

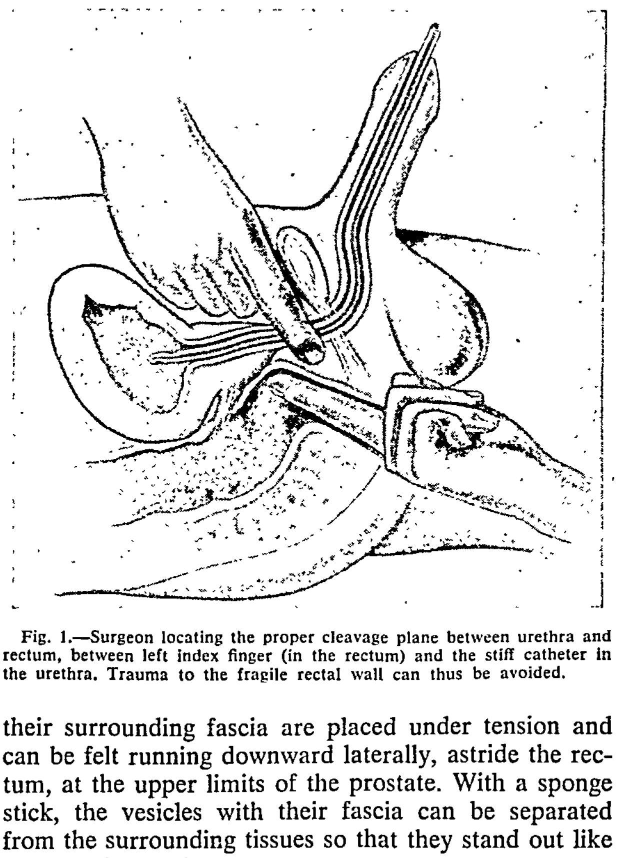

Fig. 1.—Surgeon locating the proper cleavage plane between urethra and rectum, between left index finger (in the rectum) and the stiff catheter in the urethra. Trauma to the fragile rectal wall can thus be avoided.

Brisk bleeding from the stump of the dorsal vein of the penis sometimes occurs when the puboprostatic ligaments and urethra are cut across at the apex of the prostate. This bleeding can be controlled easily with a new catheter that is passed into the penile urethra until the tip appears in the space of Retzius. This end is then grasped and pulled up behind the pubis to meet the other end of the same catheter at the tip of the penis. The two ends are clamped together and given to an assistant who then pulls directly upward (toward the ceiling) on the two ends of the catheter, thus pressing the bleeding ends of the dorsal vein of the penis against the underside of the pubis (fig. 2). If this traction is maintained for 10 or 15 minutes, the bleeding will stop.

---

[13] Jewett, H.: Radical Perineal Prostatectomy for Cancer: An Analysis of 190 Cases, J. Urol. 61:277 (Feb.) 1949.

The bladder is then opened at its junction with the prostate gland, superiorly. This incision is carried halfway around the bladder neck on both sides. Caution must be taken not to extend the incision down toward the trigone too quickly, since the ureters are then lifted upward into an exposed position by traction on the prostate gland. A new catheter can be passed through the lumen of the prostatic urethra at this point and used as a tractor to hold the prostate up. Inspection of the interior of the bladder then reveals the ureteral orifices, which can be marked with ureteral catheters during the transection of the trigone and subsequent dissection under the bladder. The trigone is cut across about one-third of the way between the internal urethral orifice and the ureteral orifices. This incision across the trigone is deepened with impunity down to the seminal vesicles and vasa, which lie between the trigone and the rectum. Care should be taken to avoid undermining the trigone, since the ureters are quite superficial at this point. It is our practice to pass a clamp upward in the midline between the two vasa at this juncture, so that each vas may be grasped and dissected out for a distance of about 2 in. (5.1 cm.) downward along the seminal vesicles. The vasa are then cut, and the ends are ligated with chromic absorbable suture. The more pliable of the two seminal vesicles is next wiped clear of its attachments to the bladder, rectum, and ureter, along with its surrounding facia. Every effort is made not to perforate this facia or to expose the vesicle, since it is desirable to remove this fascia intact. This fascia is traced down alongside the rectum to the pelvic wall, where it is grasped with a right-angle clamp, well beyond the tip of the seminal vesicle. It is then divided, and the stump is ligated with a heavy chromic absorbable suture ligature to insure against breakage in the depths of the wound. If the tie should break because of too-fragile suture material, it would be difficult to recover the stump of the vessels that led upward toward the seminal vesicle. From this point on the specimen is attached only by the remaining seminal vesicle and its fascia, which are easily dissected out, clamped, and tied well beyond the tip of the vesicle.

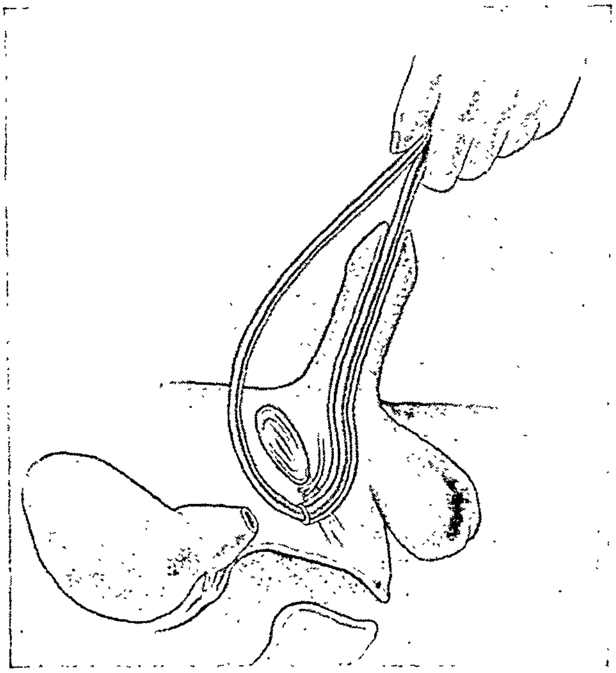

Fig. 2.—Traction upward on the urethral catheter compressing the cut end of the dorsal vein of the penis against the underside of the pubis, thus checking any bleeding from this area.

ANASTOMOSIS

Anastomosis of the stump of bladder and urethra can be carried out with three or four sutures of no. 00 chromic absorbable suture at the apex of the trigone. This maneuver is time consuming, and it is necessary that each suture, as it is placed, be separated from the others and identified by a marking clamp of distinctive type. The sutures must be tied down with great caution, so that they will not pull out of the stump of the membranous urethra. The remaining aperture at the bladder neck can then be closed from side to side.

It is our practice to insert a Foley catheter, size 22 F. with a 30 cc. bag, through the urethra at the time of this anastomosis and to bring a second Foley catheter, size 24 F., with a 30 cc. bag, out through a stab wound in the dome of the bladder. The suprapubic tube provides a safety valve and a means of introducing a new catheter, should the penile catheter become dislodged for any reason. We have found it advantageous to deflate the bag of the urethral Foley catheter within the first six hours and tape it in place. If this Foley bag is left inflated, it tends to encourage draining of urine through the operative area for a longer time than if it is deflated early. It has been our practice to leave the urethral catheter in place for 14 days.

A more rapid method of anastomosis is practiced by Flocks [8] and Chute,[10] who placed three mattress sutures through the bladder neck at the point of anastomosis, after the manner of Vest.[14] These sutures are passed out through the skin of the perineum and tied over a bit of rubber tubing or gauze. They act to hold the bladder neck directly down into the proper position and are quickly and easily placed. Some caution should be exercised in passing these needles down through the perineum, lest they run out into the skin of the thigh and become difficult to locate. It has been suggested by Goodwin that three mattress sutures be placed in the bladder neck, passed down the urethra, and affixed to the leg by a rubber-band traction device. Memmelaar sutures the bladder neck loosely around a Foley catheter and inflates the bag to 30 cc. He then pulls this bag down into the bladder neck, which holds it against the stump of the urethra. All of these various methods appear to be satisfactory. It is our practice to pass a no. 24 dilator through the urethra two weeks after the catheter has been removed and again thereafter, as necessary, if any snug point is encountered.

INCONTINENCE AFTER OPERATION

Half of our first 30 retropubic radical prostatectomies were done by resident urologists who had never done the operation before. Despite this inexperience, there were no patients with total incontinence after this procedure. One 65-year-old man has had moderate persistent stress incontinence. This record compares favorably with the incidence of incontinence after the perineal operation for radical prostatectomy. It is our hope that development of a satisfactory technique with this more familiar suprapubic route will stimulate wider application of the principle of radical prostatectomy for operable cancers of the prostate gland.

---

[14] Vest, S. A.: Radical Perineal Prostatectomy: Modification of Closure, Surg., Gynec. & Obst. 70:935 (May) 1940.

SUMMARY AND CONCLUSIONS

Radical prostatectomy for early cancer is the only available means of curing patients with carcinoma of the prostate gland. Orchiectomy, estrogens, adrenalectomy, and cortisone treatment are merely palliatives. Radioactive isotopes are under early experimental investigation. To be operable, a cancer of the prostate must be discovered early, before it causes symptoms, increases the serum acid phosphatase level or becomes fixed. Physicians who do periodic physical examinations, including rectal examinations, can save patients with cancers of the prostate by early detection of the disease. Biopsy by needle, punch, or open operation can be used to verify suspicions aroused by rectal palpation. The suprapubic (or retropubic) technique for radical prostatovesiculectomy, which does not disturb the area of the external urinary sphincter and which affords an exposure of the routes of possible metastases, is described in detail.

180 Ft. Washington Ave. (Dr. Lattimer).

PHYSIOLOGICAL AND CLINICAL ASPECTS OF CONCEPTION

Edward T. Tyler, M.D., Los Angeles

Medical research in the past few decades has made great strides, and as a result many physiological and pathological processes have been clarified to a remarkable degree. Yet, some of the most basic biological phenomena have stubbornly resisted laboratory and clinical investigation, with real progress occurring only in slow and painstaking stages. In this class is the phenomenon of human reproduction. Although there have been numerous and varied recent attempts to elaborate on the mechanism of this complicated process, there is much that is still obscure. This report reviews certain of the known aspects of normal reproduction and attempts to correlate these with a number of conditions found in clinical infertility.

In the male, endocrine stimulation from the anterior pituitary is responsible for normal testicular function, including the production of male sex hormone or hormones and sperm. The pituitary follicle-stimulating fraction (F. S. H.), under hypothalamic influence, is believed to regulate sperm production, while the luteinizing fraction (L. H.) controls the production of androgens. The scrotal location of the testes is important for preserving spermatogenesis, but intra-abdominal temperatures do not significantly affect the endocrine function. Sperm develop, undergo mitotic division, and attain a certain amount of maturation in the seminiferous tubules. They are then stored in the epididymis, where maturation continues, and they become capable of motility. The process of development of mature sperm probably requires about three weeks. In this connection, it should be noted that acute toxic influences on sperm production are not immediately evident in the semen specimen. There is a lag of at least 10 days before depression in spermatogenesis is noted, with the maximum effect observed in about four to six weeks, and then a gradual return to normal. Delayed responses of this type are of clinical importance in correlating the influence of trauma and therapy.

The bulk of seminal fluid, the vehicle for transport of spermatozoa, is provided by the prostate and seminal vesicles, under the influence of androgenic stimulation. The seminal vesicles are the source of fructose, which is metabolized by the spermatozoa for energy for motility. (Motility is still possible aerobically in the absence of fructose.) In view of this close relationship between fructose secretion and androgenic stimulation of the seminal vesicles, a seminal fructose test has been proposed to evaluate male hormone activity.[1] In normal males, the seminal fructose level varies between 200 and 700 mg. per 100 cc., whereas in persons with androgenic deficiency the values are often below 200 mg. per 100 cc. The majority of patients seeking treatment for infertility, however, are not hypogonadal from an endocrine standpoint, and comparison of seminal fructose levels in fertile and subfertile men fails to show any marked difference. Most subfertile husbands erroneously assume that their relative infertility implies lowered "virility." It is clinically important to impress these patients with the fact that the two functions of the testes are separate and that (as is usually the case) their glandular output is normal. Emphasis on this distinction will in some instances help dispel the feeling of inadequacy suffered by these patients.

The transport of spermatozoa from male to female by means of the ejaculatory process is a relatively complex mechanism, involving cerebrocortical and spinal neurological components, and depends on adequate androgenic function. Such coital disturbances as premature ejaculation are generally insignificant as etiological factors in clinical infertility, as long as the semen is deposited intravaginally, unless they interfere appreciably with the frequency of intercourse.

[1] Landau, R. L., and Loughead, R.: Seminal Fructose Concentration as Index of Androgenic Activity in Man, J. Clin. Endocrinol. **11**: 1411, 1951.

Spermatozoa, when deposited in the vagina, are placed in a physiologically hostile environment. The normal vaginal pH is approximately 4.5, a degree of acidity too high to favor sperm viability. The latter do best in a slightly alkaline medium, such as the pH of 7.5 usually found in semen. It is rare to find semen specimens of low pH, even in instances of severe male infertility. This stability of the pH is generally undisturbed even by chronic infections of the accessory sex glands. Infections of the vagina usually produce elevation of the pH and accordingly do not contribute to diminished fertility on the basis of acidity.

The hostile environment encountered by spermatozoa in the normal vagina is offset to a large extent by the buffering capacity of the semen. Effective buffering ordinarily permits survival of adequate numbers of sperm sufficient long to allow penetration of the cervix. In spite of buffering, however, spermatozoa soon lose their viability in the vagina; therefore, prompt spermigration is essential for reproduction.

It has long been believed—although some current investigators dispute this—that the vaginal pH is maintained at an acid level by the action of the normal bacterial flora, chiefly Doederlein bacilli. These organisms act on glycogen, breaking it down to lactic acid and carbon dioxide. The resultant acid environment is favorable to the growth of Doederlein bacilli and unfavorable to many pathogenic organisms. Hence a paradoxical condition exists in the vagina, where the pH is optimal to maintain a normal healthy flora yet too low to favor survival of the cells essential for reproduction. Cervical secretions, on the other hand, generally exhibit a pH of approximately 7.5, and are accordingly more favorable to spermatozoa. It is possible that this difference in the pH is one of the factors that favors migration of the sperm from the vagina into the cervix, although it does not explain further directional progress in the upper genital tract. Bickers believes such progress depends to a considerable extent upon contractions of the uterine musculature, and attributes certain cases of infertility to myometrial dyskinesia at the fertile time of the cycle.[2]

The cyclic variations that occur in cervical secretions are quite marked, and many of the changes have been elaborately detailed by Pommerenke and his associates.[3] Near ovulation, the secretions are thin, abundant, and rich in carbohydrate. During this phase cervical mucus exhibits pronounced fern-like crystallization, a phenomenon that may readily be observed by spreading a thin film of mucus on a slide and allowing it to dry. At this stage of the cycle, cervical secretions are most receptive to spermatozoa. During other phases of the cycle, the physical characteristics of cervical mucus are relatively unfavorable for sperm penetration, a situation that implies the correlation of fortuitous circumstances at the specific time when conception is possible.

Many investigators believe that the factor of abnormal cervical secretions is the commonest single cause of infertility. Specific treatment with antibiotics is indicated in certain types of cervicitis, but procedures such as extensive cauterization can cause irreparable harm by destroying the cervical glands. (This type of conservatism should also apply to certain other vague and more extensive surgical procedures used in the treatment of infertility, since there are still too many "unknowns" in the cause of barren marriages to warrant resort to radical therapy by a process of elimination.) Estrogenic therapy has been employed to alter the secretions favorably for spermigration, but, since large doses may inhibit ovulation, the amount given should be carefully regulated. A daily oral dose of 0.1 mg. of diethylstilbestrol or the equivalent in other estrogens is frequently used to increase cervical secretion.

It is interesting to note that when sperm motility is observed in seminal fluid, there is very little evidence of any straight directional course. Vigorous, scattered motility occurs in many directions, and it is my opinion that attempts to define types of directional motility in the semen as normal or abnormal are futile, as long as such motion is highly active. The quality of motility in normal cervical secretions, however, is quite different, for in this medium spermatozoa generally show a definite, forward, directional progress. Whether this is due entirely to the physical characteristics of cervical secretions, or whether it is due to a chemotaxic effect, is highly conjectural. Since sperm microscopically observed in cervical mucus are removed from the genital tract, one might assume that any effects are directly attributable only to the surrounding medium.

Survival of spermatozoa in the female genital tract has been the subject of considerable speculation. After intercourse, during the ovulatory phase of the cycle, viable spermatozoa can generally be found in the cervical canal for 48 hours and occasionally considerably longer. Viability of sperm in the upper portions of the genital tract has been estimated to be as long as five days, but this does not necessarily imply a fertilizing capacity for that length of time. In lower animals it has been shown that the fertilizing capacity of spermatozoa can be destroyed without concomitant loss of motility.[3a] The life of the ovum, from the standpoint of fertilizability, has been estimated to be no longer than 24 hours, based on observations in other species.

Experimental evidence indicates that the time required for progress of sperm from the cervix to the fimbriated ends of the fallopian tube is probably only a few hours. Brown, for example, during laparotomies, found that sperm were obtainable in the tubes three hours after they were placed in the vaginal canal.[4] This prompt sperm migration would tend to indicate that intercourse timed very close to ovulation would be most advantageous from the standpoint of insuring conception. Delay in spermigration or ovum transport may be due to abnormal tubal peristalsis, a condition that can be demonstrated by kymographic carbon dioxide insufflation or fluoroscopic study.

The union of sperm and egg is believed to take place in the outer portion of the fallopian tube, near the junction of the distal and middle third. Seymour and Benmosche, in electron microscope studies of spermatozoa, have suggested that the heads of these cells have a small cup-like area, which is possible significant as a point of contact for sperm and egg.[5] We have also noted this same consistent concavity in the sperm head.[6]

The presence of the egg at the site of ovulation is the culmination of a sequence of events that includes preliminary maturation of a graafian follicle in the ovary under the influence of anterior pituitary gonadotropic stimulation. The three hormones that are now believed to comprise gonadotropic secretion (follicle-stimulating, luteinizing, and luteotropic) act in coordination to effect maturation of the follicle and its rupture and corpus luteum formation and function. Failure of ovulation is one of the common causes of infertility, but its incidence is undoubtedly not as high as was formerly believed. Attempts to induce ovulation with gonadotropins are generally clinically disappointing, but occasionally the use of estrogens during the major portion of one cycle may result in ovulation in the succeeding cycle.

Migration of the egg into the fimbriated end of the fallopian tube, following its extrusion into the peritoneal cavity, is a process that may have chemical aspects in addition to such obvious physical factors as peritoneal currents. Whether or not there is active participation on the part of the fallopian tube in the process is another matter for speculation. In rabbits, a portion of the tube apparently surrounds the ovary at ovulation to facilitate transport.[7] In humans, Decker has reported culdoscopic observations indicating motility and change of size of the ovarian ligaments near ovulation, factors that he considers favorable to ovum receptivity by the tube.[8]

The corpus luteum, formed at the site of ovulation, functions for a little over a week in the nonpregnant cycle and then deteriorates. Should pregnancy intervene, this endocrine gland undergoes further development and is an important source of hormones during pregnancy. It is not indispensable to pregnancy, for gestation has continued even when this gland has been removed. Much of its function can be carried on by the placenta after this structure has become adequately developed.

Following fertilization, the egg is carried by peristaltic action into the body of the uterus, where nidation takes place, approximately six days after fertilization. At this time, the fertilized egg elaborates enzymes that help erode the surface of the endometrium for implantation. The products of erosion probably also provide nutrient for the developing egg. Decidual changes in the endometrium and subsequent placental formation result indirectly from continued endocrine stimulation in amounts far above those found in the nonpregnant state.

SPERMATOZOA REQUIREMENTS FOR CONCEPTION

There has been much speculation concerning certain mechanisms involved in conception. For example, in view of the need for only one sperm for fertilization, one cannot but wonder at the millions of spermatozoa present in the average ejaculate. Several years ago, it was suggested that one reason for this abundance was the necessity for obtaining adequate hyaluronidase at the site of fertilization. This enzyme, carried by the sperm head, was thought to be essential for fertilization in denuding the egg of its follicular cells. More recently it has been shown experimentally that removal of these cells is not essential for fertilization and that spermatozoa can reach the ovum through intact follicular cells. Clinically, despite initial enthusiasm, hyaluronidase has not been found effective as a therapeutic agent in sterility.[9]

Chang,[7] in studies of rabbit fertilization, has given some indication of another possible reason for the large numbers of spermatozoa in the ejaculate. On the basis of microscopic examination of serial sections of tubes, after insemination, he estimates that only 1 out of 100,000 sperm reaches the site of fertilization. This would tend to indicate that there is less of a superabundance of sperm than we have believed.

There have been a number of conflicting reports in the literature concerning the lower levels of seminal values at which pregnancy can occur. One often reads reports by investigators of conceptions occurring when the husband's sperm count is as low as 500,000 per cubic centimeter or even less. It is my opinion that conceptions at such figures, if they occur at all, are extremely rare. In table 1, 164 pregnancies, which occurred during the course of therapy of 570 subfertile couples, are analyzed from the standpoint of semen levels at which conception occurred. The maximal sperm count noted during investigation is the factor that determined in which category the husband should be placed. The 73 husbands who had consistent counts no better than 20 million per cubic centimeter were responsible for only two conceptions (2.7%). The group in which the sperm count varied between 20 and 40 million achieved a conception percentage of 15.5%, a significantly lower figure than the 26.9% level in the 40 to 60 million group. When the count was 60 to 100 million, the pregnancy rate was decidedly better (36.0%), but not much different from the group with counts of 100 million or higher (38.8%). This would tend to give some support to the figure of 60 million per cubic centimeter as the lower limit of normal sperm concentration.

Table 1.—*Percentage of Conceptions Known to Have Occurred at Various Sperm Count Levels**

Level of Sperm Count, Millions per Cubic Centimeter	No. of Patients Treated	No. of Pregnancies	Percentage of Conceptions
100+	201	78	38.8
60-100	136	49	36.0
40- 60	89	24	26.9
20- 40	71	11	15.5
1- 20	73	2	2.7

* The sperm counts shown were the best observed while the couple was under investigation.

It may be argued that the low incidence of conceptions at the lower sperm count levels in this series might be attributed to subfertility in the wife. However, this is negated by the fact that a number of the wives in this

group promptly became pregnant when donor insemination was employed. A series of semen analyses was obtained on one patient who received various types of therapy for almost two years and whose counts ranged between 2 and 28 million. When donor insemination was resorted to, pregnancy occurred after a single insemination. If diminished fertility of the wife had been a factor, it is highly improbable conception would have occurred so readily. It is possible that reports of conceptions occurring in the presence of extremely low sperm counts do not take into consideration the marked fluctuations that can frequently occur in semen values in the same person. The specimen examined may not necessarily bear a close relationship to the semen level at the specific time of conception.

Efforts to increase spermatogenesis in the infertile male are generally not very successful.[10] In the last few years many methods of treatment have been hopefully advanced, but the extremely oligospermic husband remains a therapeutic problem. Certain types of empiric medication, such as the routine use of thyroid, are probably valueless.[11] The most significant recently advanced therapy has been the use of testosterone "rebound." This treatment involves preliminary suppression of spermatogenesis by testosterone, to the point of complete azoospermia. After an interval of one-half year to a year and a half, rebound to normal sperm production should occur in properly selected cases.[12] However, of 21 men I have treated thus far, not a single one has shown the anticipated rebound in repeated observations for as long as two years.

TIMING OF CONCEPTION

In view of the clinical importance of determining the time of ovulation, as well as its occurrence, the use of basal body temperature charts has become relatively widespread in infertility practice. Many patients have been taught to utilize these charts as absolute guides for timing intercourse and intervening periods of continence. It has been commonly accepted that ovulation occurs near the thermal shift in the chart and that other phases of the cycle are relatively or completely infertile. On a theoretical basis, the use of these charts would seem quite valuable. From the practical standpoint, however, there is considerable limitation to their usefulness. One obvious drawback is the fact that many charts kept by infertility patients show a grossly irregular pattern that defies interpretation. In these it is often impossible to pick the definite time of thermal shift, even when a shift occurs. A dip in temperature supposedly occurs prior to the rise, which is presumably characteristic of ovulation, but only an occasional chart shows this. Many investigators feel that the temperature shift bears no consistent relationship to ovulation, in that the latter phenomenon can occur several days before the temperature changes or even after it.

My own impressions concerning the time of ovulation are derived by inference from the charts of patients in whom donor insemination was employed only once in the cycle in which conception occurred. The husbands in this series were completely infertile because of azoospermia, and therefore it would be reasonable to assume that pregnancy occurred as a result of the single insemination. (The scope of this report does not permit a discussion of the various moral and legal aspects of donor insemination, but these statistics are presented for what data they may add to the problem of determining the time of conception.) In a series of 29 conceptions one occurred when insemination was performed as long as five days before the temperature rise, three resulted from insemination four days before, and one occurred four days after the shift. Most conceptions occurred in the interval between two days before and two days after the rise, but this does not necessarily imply as great a difference as it would seem, in view of the proportionately larger number of inseminations done on these days. One patient—apparently highly fertile—became pregnant three times, with the use of a single insemination on each occasion. The first two inseminations were done three days before the temperature shift, while the third was performed four days before the temperature rise.

It may, of course, be questioned whether ovulation or fertilization necessarily occurred near the time of insemination in these cases. If a limited period of fertilizing capacity of sperm or fertilizability of egg is assumed, the time relationship probably exists. It is possible, however, that both these cells may exhibit marked variability as far as fertilization is concerned. It is also possible that intercourse can stimulate ovulation, a situation that occurs in some lower animals. In the instances where artificial insemination was used, coital stimulation would not be a consideration, unless intercourse with the husband occurred at approximately the same time. Another factor is the possibility that certain constituents of the semen may exert a physiological action in the female. Current laboratory studies on the protein constituents of semen have indicated certain effects on the female genital tract, but whether these are clinically significant is difficult to ascertain at present.[13]

THERAPEUTIC EFFECTS OF ARTIFICIAL INSEMINATION

There has been a great deal of controversy concerning the value of artificial insemination with the husband's semen. This procedure is often employed when oligospermia is present, as well as in cases where there is no seminal inadequacy. Since the two groups present different situations, they should be considered separately.

A total of 1,086 instances of artificial inseminations were reviewed. In the group with normal semen, conceptions occurred in 42 cycles in which artificial insemination happened to be employed and in 38 cycles during which no inseminations were done. While individual factors varied, the wives were a basically similar "functional" group and hence the statistical comparison, though limited, is probably significant.

In many of these instances insemination was employed as a possible method of circumventing cervical hostility, but apparently instilling the semen low in the cervical canal does not correct this factor. Certainly the results fail to show any therapeutic effectiveness attributable to artificial insemination when the semen is normal.

[13] Singher, H.: Personal communication to the author.

In the group of oligospermic men, the data suggest that pregnancy is more readily possible with the use of artificial insemination (table 2). Of 33 conceptions that were reviewed in this group, 21 occurred in cycles during which insemination was employed and 12 in cycles during which insemination was not done. The apparent increased effectiveness in the oligospermic group may lie in the fact that insemination using the cervical cap or speculum technique prevents a certain amount of inactivation of spermatozoa by the vaginal secretions, and this may be significant when reduced numbers are present.

In this group insemination was often done alternately with the cervical cap and without it in the same cycle, and no data are available concerning the relative merits of these procedures. When the cap is utilized, care must be exercised that the semen does not leak out during insertion; otherwise the device may inadvertently serve as a barrier to contact of semen with the cervix. Properly used, the cervical cap helps to provide more prolonged contact of semen with the external cervical os.

"CONCEPTION-LESS FERTILIZATION"

As outlined previously, implantation of the fertilized egg in the endometrium depends on adequate transport of the fertilized egg through the tube and into the endometrium, together with the initiation of trophoblast enzymatic activity at a time when the endometrium has been adequately prepared. In some obscure instances of infertility, where no obvious pathological conditions are found, it is possible that fertilization may occur but the fertilized egg is unable to implant itself in the endometrium and menstruation occurs on schedule. The term "conception-less fertilization" may be loosely assigned to this problem, because conception—a term that implies lodging of the fertilized egg in the uterus—has not taken place. These patients may be found to have poor progestational endometriums on repeated biopsy, and abnormal basal temperature charts in the luteal phase, showing short or gradual elevations. Since the inadequately developed endometrium may be a result of poor corpus luteum function, large doses of progesterone should be given, together with estrogens (1.5 mg. of Estrotate [estradiol-3-trimethylacetate] and 15 mg. of progesterone intramuscularly daily would be an average dose). Substitution therapy of this type may inhibit a certain amount of gonadotropic stimulation, and accordingly chorionic gonadotropin is also employed. If oral medication is used, the doses must be very large; 75 mg. of ethisterone (Pranone) together with 4 mg. of estradiol trimethylacetate should be considered a minimal daily dose. Chorionic gonadotropin (1,000 I. U. on alternate days) can be given only by injection. Occasionally this type of therapy will delay the onset of menses, but this delay can generally be differentiated from pregnancy by an atypical fluctuating basal temperature curve that fails to show the persistent elevation noted during pregnancy.

Poorly developed endometriums at the time of nidation in certain instances of habitual abortion may also be a factor. Adequate preconceptional investigation, including endometrial biopsies and determination of pregnandiol values, may direct attention toward this type of deficiency. Although results of any type of therapy in habitual abortion invite skepticism on a purely statistical basis, treatment of these patients, initiated prior to conception, and particularly in the second half of the cycle in which pregnancy is attempted, merits consideration. Hughes, in his preconceptional treatment clinic, has investigated the endometrial phase of the infertility problem in great detail and his therapeutic accomplishments are very encouraging.[14]

STERILITY OF UNKNOWN CAUSE

Even in a specialized infertility practice, a large majority of the patients studied fail to become pregnant despite all therapeutic attempts. This group not only emphasizes present diagnostic limitations but also points out the need for systematic investigation of the infertility problem by men willing to devote adequate time to it. Perhaps some of the newer methods of observation may prove helpful by providing information concerning such factors as migration of the egg from ovary to tube, or minor structural changes in the genital tract that can interfere with conception. Certain types of infertility, notably "one-child sterility," long thought to be attributable to cervical trauma or tubal pathology, may prove to have an immunological basis. This possibility is not too remote when one considers that rabbits, for example, have been experimentally immunized to the antigenic components of human or rabbit sperm. The actual process of fertilization may prove to be basically an immunologic phenomenon, as advanced by A. Tyler.[3a] The elaboration of these mechanisms in experimental animals will undoubtedly shed more light on some of the problems encountered clinically.

TABLE 2.—*Relative Incidences of Conception When Artificial Insemination Was Utilized and Not Utilized in Women with Normally Fertile Husbands and Women with Oligospermic Husbands*

	Normal Semen	Oligospermic Semen
No. of conceptions when insemination was employed................	42 (52.5%)	21 (63.6%)
No. of conceptions when insemination was not employed...........	38 (47.5%)	12 (36.4%)

There is much that is still obscure in the mechanism of conception and in many basic problems of sterility. In a specialized sterility practice today, it is unlikely that more than one out of every three couples with a true sterility problem can be helped. This is probably an accurate figure, if those patients are excluded who prematurely seek medical advice and receive therapy long before there is any need for it. Uniform criteria for effectiveness and pooling of results would be highly desirable in this field of medical practice in order to obtain a true and adequate appraisal of clinical results.

SUMMARY

The physiology of conception is reviewed, with reference to certain specific aspects of the problem of sterility. Studies on approximately 4,000 semen specimens indicate that pregnancy is highly unlikely when the sperm count remains consistently below 20 million. Despite encouraging recent reports of treatment of male infertility, there is no real solution for this problem at present.

---

[14] Hughes, F.: A. M. A. Scientific Exhibit, 1952.

The day of basal temperature shift may not necessarily coincide with ovulation, and therefore should not be used too arbitrarily as a guide to timing coitus in treatment of infertility. Single donor inseminations have resulted in pregnancies as long as five days before the temperature rise in women with azoospermic husbands.

A cause of sterility that may be overlooked in certain apparently normal women can be somewhat loosely termed "conceptionless fertilization." This involves failure of implantation after the egg has been fertilized. In such cases treatment should be intensive during the second half of the cycle, with therapy directed toward improving endometrial quality. In certain types of habitual abortion, similar therapy should be given prior to conception.

10911 Weyburn Avenue (24).

ACADEMIC FREEDOM IN MILITARY MEDICAL RESEARCH

Howard T. Karsner, M.D.
and
Commander Robert A. Phillips (MC), U. S. Navy

From the times of origin of universities down to the present, academic freedom has been a topic of concern to instructional staffs, administrators, and the public. To discuss its various meanings would lead to a consideration of semantics far beyond the compass of this paper. For our purposes it is enough to say that academic freedom implies in the minds of most moderns the right and duty of teachers to present the truth as it is currently conceived. Among military personnel freedom of teaching can be exercised in the many courses of instruction given in the services and especially in the influence of the more senior investigators on their younger colleagues and pupils. We consume research talent, and effort should be made to replenish and enlarge the supply of investigators. To do so requires freedom for both seniors and juniors.

SECURITY AND PUBLICATION

Freedom, however, has a broader connotation than the adjective "academic" permits. Freedom in science should grant the power to choose, to think, to try and fail, and the privilege of intellectual liberty. All investigators owe to science the obligation to disseminate results. Here the military investigator is sometimes at a disadvantage as compared with his civilian colleagues because he is faced by the bugbear of classification. He is not free to publish material that higher authority declares secret, confidential, or restricted. Nor is he always clear as to why the classification is imposed. This handicap is recognized, however, by many who have thought the matter through. In one of the Steelman reports there is a discourse on security versus scientific freedom. "A security policy should be developed in relation to science which will permit the maximum opportunity for creative endeavor and freedom in dissemination of results consistent with national security. This requires continuing review as the situation changes." Henry D. Smyth of the Atomic Energy Commission states that a large part of the work of AEC's division of research is unclassified and says that "the decision to handle this work without secrecy comes from the conviction that secrecy retards progress." Admitting that classification may be necessary for some work at some time, we believe that continuing review and revision are of paramount importance.

The very nature of military research cannot permit the same freedom of choice in investigative projects that is allowed the civilian except as may apply perhaps in some of the commercial and industrial establishments. Even in the latter, however, freedom is becoming greater as industrialists recognize the fact that, as stated by Brig. Gen. David Sarnoff, "progress is our most important product," and progress is made only by research and development. By and large, the civilian takes up projects of interest to him, some problem initiated by his innate intellectual curiosity. This is not denied the military investigator, but in many instances cannot be granted to him.

VALUE TO HEALTH

Medical departments of the services are charged with promotion of the health, safety, and efficiency of the personnel. The research effort has the same objectives and similarly is often applicable to both military and civilian medicine. President Truman in his address to the 1952 meeting of the Association of Military Surgeons said, "the advances we have made in improving the health of the American people are, in great measure, the result of steady progress in medical research." Admiral Pugh, at the same meetings, evidently reflecting the views of all three Surgeons General, said, "medicine . . . will remain alive and progressive commensurate with the degree in which it engages in research." Whether research is conducted in military laboratories and hospitals or by contract in civilian institutions, freedom in research is essential. Administration is necessary but should be tempered to the requirements and freedom of the research workers. "Housekeeping," provision of supplies, personnel management, and the like properly belong in this field. It would be well if the military administrator could have a background of research, but he, in any event, must have sympathy with it. He must cooperate with the research staff to the extent of granting all freedom possible.

Medical Research Adviser to the Surgeon General, U. S. Navy (Dr. Karsner).

Read before the Section on Military Medicine at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

The opinions or assertions contained herein are the private ones of the authors and are not to be construed as official or reflecting the views of the Navy Department or the naval service at large.

RECRUITMENT

The support of military medical research is by public funds, and its justification lies in convincing those who administer appropriations that it is to the ultimate advantage of the combatant forces and the nation. The research problem may be set up because of requirements or needs of some agency of the armed services or the investigator may propose a project based on his own knowledge of these needs and requirements. Big or little as the problem may be, the answer can best be given by the highest grade research workers who can be obtained and retained. To obtain and to retain such persons are two closely integrated facets of the same situation and apply to the military services even more stringently than to other organizations. Various factors play a part; income, security of tenure, retirement, financial resources for material, equipment, congenial atmosphere, and other factors enter the picture, but to the highly qualified investigator the greatest of all is freedom.

Anyone entering on a career in military medical research must have the good sense to realize that the primary mission is military. He should familiarize himself with military operations in order to understand why his projects are of importance, and he should be free to go into the field in order to gain intimate acquaintance with operational activities.

How then can freedom be offered as an inducement to enter and stay in military research? Our answer is simple enough. The best man for the mission is the best man obtainable. And the best man cannot be confined to answering questions by using only methods and procedures already in effect. The best man appreciates the need for practical answers, but he cannot make his best contributions if that is all he is allowed to do. He cannot be the best man if he does not see beyond the immediate problem to others that underlie it and that may provide the basis for an answer. This leads him into unexplored fields; he delves into basic research. It might well be said that basic research is the function of the universities and research institutes, but here we deal with the practical matter of obtaining and retaining the best investigators, and the best have a certain devotion to enlarging the field of human knowledge. The Steelman report divides basic research into (*a*) fundamental research and (*b*) background research. Background research uses known principles to reach clearly defined objectives. More simply stated, it directly supports applied research. Not infrequently an investigator finds that there are gaps in information necessary to solution of his problem and he must fill the gaps himself. Fundamental research extends knowledge of general principles governing natural phenomena and that alone. If that knowledge proves to be applicable, it is a by-product rather than an aim. Fundamental research cannot be "directed," cannot be judged by results, cannot go by a timetable, and cannot be productive without great freedom.

ADMINISTRATIVE APPROACH

There are different ways in which military medical research is practiced, and in each the matter of freedom is involved. One method is by direction from a central office. Scientists and administrators in such an establishment have a broad over-all view of military requirements and are familiar with the supporting budgets. A potential disadvantage is that the investigator may be restricted in his free choice of problems and in his opportunity to conduct background and fundamental research.

In contrast is the freedom implied by initiation of projects in the periphery, that is, in the hands of the investigators in laboratories and other installations of the medical departments. The advantage lies in the fact that, generally speaking, the best research is that which originates in the mind of the scientist. This may well be the most scientific mode of approach, but when all aspects of military research are considered it cannot always be practiced. The military establishments must have a program of research, which naturally applies to the individual establishments, and the investigators are somewhat limited in freedom because of the necessity for fitting the projects into the program.

Another point is the relative merit on the one hand of task forces or expeditions and on the other hand of the permanent installation in the field. The task force may be handicapped as to freedom by limitations of scope and time, but materials and ideas brought back often provide for relative freedom and certain valuable results. The fixed installation permits more freedom than the task force. It fits into the over-all objective yet can take advantage of conditions in and peculiarities of the local environment and can seize opportunities that may not be readily apparent to a central group.

The services also avail themselves of contracts with civilian institutions. The disadvantages lie in less direct control by the military and less contact with operational requirements and the difficulties of dealing with classified topics. There are, however, definite advantages in that basic research can be encouraged, that highly specialized information can be provided, and that expensive equipment may be more readily available than is true in the services. Contractual research can be complementary to military research, and there can be a free interchange of ideas and results.

CAREER PATTERNS

Even though it may be necessary for the operational requirements of the services, the transfer of military personnel from one station to another often limits freedom in research and prevents actual continuation of certain studies. This situation could be corrected in large part by the establishment on a reasonably firm basis of career patterns in research for the armed forces.

Conscientious aid, advice, guidance, and coordination are provided by such agencies as the Research and Development Board of the Department of Defense, the National Research Council, and comparable bodies in the three services. Thus, there is assurance that military medical research will be purposeful and productive, that extravagance will not be tolerated, and that needless duplication will be avoided. Only by research can we keep abreast of friendly nations and progress further than our potential enemies. And only by freedom commensurate with national policy can this research be most productive.

Bureau of Medicine and Surgery, Department of the Navy (Dr. Karsner).

PRESENT STATUS OF OPHTHALMIC JOURNALISM IN AMERICA

CHAIRMAN'S ADDRESS

Francis Heed Adler, M.D., Philadelphia

Ophthalmic journalism in this country has now attained world leadership. It is time to evaluate how well it is meeting its present obligations and to consider in what ways it should develop. As one looks at the past of ophthalmic journalism, it seems that it has had no very proper upbringing, but like Topsy, "just grew."

The first American journal devoted to ophthalmology appeared in 1862, edited by Julius Homberger. This journal was called the *American Journal of Ophthalmology*, but was not even distantly related to our present American journal, and, according to good authority,[1] it was "short-lived" and "ill-famed." It lasted only two years. The oldest publication in existence today is the *Transactions of the American Ophthalmological Society*, which first appeared in 1864. Fifty volumes have been published to date, containing some of the best work done in this country. The *Archives of Ophthalmology* followed in 1869, with the title *Archives of Ophthalmology and Otology*, under the editorship of Herman Knapp, who not only was a distinguished ophthalmologist, the founder of the New York Ophthalmic and Oral Institute, and the first chairman of the Section on Ophthalmology but also had the especial honor bestowed on him by Providence of being the father of Dr. Arnold Knapp.

Another *American Journal of Ophthalmology* appeared in 1884. In 1917 it absorbed three of the then existing journals—the *Ophthalmic Record*, the *Annals of Ophthalmology*, and *Ophthalmology*—and became an entirely new journal under the editorship of Edward Jackson. Under the aegis of outstanding editors, this has grown to be our present great *American Journal of Ophthalmology*, with Dr. Derrick Vail as its able and dynamic editor. As stated, the *Archives of Ophthalmology* was first published as the *Archives of Ophthalmology and Otology*, but in 1879 the two sections split and the *Archives of Ophthalmology* continued alone. This journal was the direct descendant of the German journal *Archiv fur Ophthalmologie*. Following his father, Dr. Arnold Knapp continued to publish the *Archives of Ophthalmology* privately until 1929, when the ownership was transferred to the American Medical Association, and this journal became one of the A. M. A.'s special journals.

Table 1 shows all the journals that have been started since 1862 in chronological order. Those still being published today are marked with an asterisk. Of the 27 periodicals, only 13 are still in existence. Table 2 shows the number of journals started in each decade, from 1860 to date, and the number still in existence. There is no evidence that journals were begun in response either to the growth of scientific organizations or to the number of men practicing ophthalmology. The greatest increase in number of journals came around 1900, and since then the number of new journals has gradually fallen off. It seems evident that the point has been reached where supply and demand are about balanced.

It is difficult to determine whether there has been an increase in reading interest in periodicals. The chart shows the increase in the number of paid subscribers of the *Archives of Ophthalmology* since it was taken over by the American Medical Association. Dr. Vail tells me that these figures are similar to those of the *American Journal of Ophthalmology*. These cannot be construed as proving an increase in reader interest, since this could only be judged by comparing the circulation figures with those showing the increase in the number of ophthalmologists in this country during the same period. When comparing the circulation figures with the number of candidates who applied to take the American Board of Ophthalmology examination in the same period of time, one finds the increase in subscribers about matches the increase in number of men applying to take the board examinations. This presumably means that the increase in subscribers is due partly to the increase in the number of potential readers and not entirely to reader interest.

FUNCTIONS OF AN OPHTHALMIC JOURNAL

What are the functions of an ophthalmic journal, and how well do the 13 periodicals now in existence carry out these obligations? There are a number of tasks that scientific periodicals should fulfill. Obviously, it would be a waste of paper if each journal undertook all of these. Some specialization must necessarily develop, if not by design, simply by natural selection, for no one journal could possibly do all the jobs equally well. I conceive the following as the most important of these tasks: 1. First is the publication of original scientific manuscripts that present the results of laboratory and clinical research and descriptions of new instruments and other means of therapy. 2. Next is the recording of rare or new disease entities. 3. Another task is reviews of specific subjects, bringing knowledge of the subject up to date and developing concepts for further research. 4. Abstracts of current literature are important, especially the foreign literature, which might not be easily available to the average ophthalmologist, and literature from journals other than ophthalmologic containing articles of interest to ophthalmologists, for example, the basic science journals and special journals in other fields related to ophthalmology. 5. Annual reviews, covering the whole of ophthalmology should be made, providing a suitably annotated compendium of what was reported during the past year in each particular field. These reports should be done by an expert in each field, who would purposely inject his own criticism into the report, confirming this with appropriate data. The reader would thus enjoy the benefit of seeing the field through the eyes of an expert,

[1] Verhoeff, F. H.: American Ophthalmology During Past Century, Arch. Ophth. 39: 451-464 (April) 1948.

and would be less likely to be misled by reports that only an expert could properly evaluate. 6. Reviews of books may range from a simple notice of publication to a lengthy critical analysis of a book. Such reviews would best not be signed, in order to allow the reviewer freedom to express an opinion. 7. News, announcements of meetings, reports of meetings with discussions of papers presented, obituaries of prominent men, honors bestowed, and appointments to teaching positions and specialty boards all fall within the province of a journal whose job it is to disseminate such news. 8. Editorials may be of almost any nature, ranging from impersonal comment of general interest to a biased stand on some controversial subject with the avowed intention of molding public opinion. 9. Letters to the editor generally take the form of criticizing some article previously published in a particular journal. It would seem only fair to allow the author criticized an opportunity of a rebuttal in the same journal, preferably in the same issue. 10. Historical, sociological, and other cultural data pertaining to ophthalmology should be published. 11. Symposiums, such as the valuable contributions made during the past few years by the Academy of Ophthalmology and Otolaryngology and published in the transactions under Dr. Benedict's direction should be published. Monographs that could not find an outlet through commercial publishing houses are also suitable for publication.

Table 1.—*American Ophthalmologic Journals*

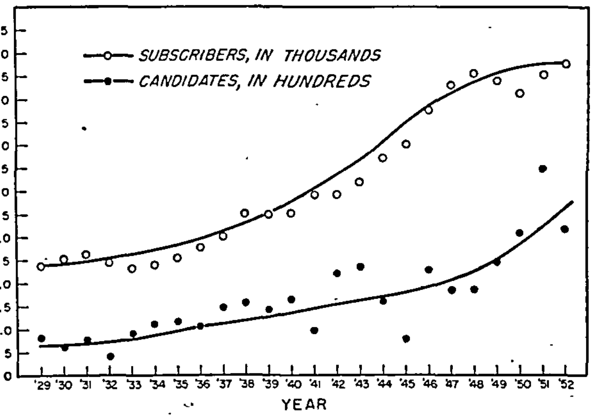
1950-	1	1

FUTURE DEVELOPMENTS

It may be said that all the functions listed are being satisfactorily performed by the existing journals, but I would like to point out some deficiencies and suggest ways by which these services might be improved. The most important function of a scientific periodical is the publication of scientific papers. Although the publication of a manuscript in a journal does not necessarily guarantee that the facts it sets forth and the conclusions drawn by the author are correct, or are even agreed to by the editorial board, publication itself sets a value on the paper in the eyes of the readers to the extent that it has met the standards for acceptance of that journal. In the basic sciences these standards have always been high, and it is unusual for an article to appear that does not have merit. The readers expect that the judgment of the editorial board will be good, and if unworthy manuscripts are frequently published, the journal's reputation soon suffers. It is curious that this same feeling of responsibility on the part of the editorial board has not dominated journals in the clinical fields to the same extent that it has in the basic sciences. It is high time that it does so. The subscribers to an ophthalmologic journal have the right to expect the same careful scrutiny of all papers by the editorial board and rejection by that board of any paper that fails to give reasonable evidence



Comparison of number of subscribers to ophthalmic journals and the number of candidates who applied to take the American Board of Ophthalmology examination from 1929 through 1952.

on which the author's conclusions are based. We have all seen manuscripts published in which claims were made for the successful treatment of some disease without adequate proof being submitted by the author. This usually consists of failure to provide suitable controls or lack of proper statistical analysis of the data, as I have pointed out in previous editorials.[2] A shocking example of this was the recent publication of an article[3] claiming successful treatment of cataracts with fish lens protein. There was not the slightest evidence presented in this paper to substantiate the author's claim. No rebuke can be too severe to an editorial board that allows such an unworthy article to be published, especially when, as in this case, the claims were of such widespread public interest that they were picked up and heralded by the lay press throughout the country.

Another obligation of a journal is the rejection of manuscripts that contain nothing new and that merely burden the reading public with a rehash of what probably has been better written before. Unfortunately, publication is too often just as easy for the person with a desire to advertise himself as it is for the author who has something to contribute to his fellows. It is the moral obligation of a journal to reject scientific "potboilers" regardless of how illustrious the author may be. Perhaps the easiest way to lose friends is to become a chief editor.

Publication of papers is one of the chief ways by which a physician attains prominence among his colleagues, who too often thoughtlessly consider quantity of publication rather than quality the criterion by which to judge him. Let us beware of the prolific writer whose pronouncements contain very dilute solutions of thought. Let editorial boards in particular protect the reader from too ambitious authors. The sole purpose of authorship should be to share things of value. In its early days a local medical society, to which I still belong, used to fine its members $25 if they did not publish at least two papers each year. I am inclined to believe that it would now be appropriate to fine each member $25 for each paper in excess of two published during a year.

Finally, the editorial boards of all the journals in this country should be in frequent communication with each other to review problems that are vital to ophthalmology and to agree among themselves how each should specialize and how each can be helpful for the good of all. No new journal should be contemplated without mutual approval. Overspecialization has its dangers. To start a new journal for neuro-ophthalmology, for strabismus, or for research saps some of the strength of each of the existing journals and should be permitted only if it can be shown that the good that would follow compensates for the harm done. It is pleasant to think that ophthalmology is being well served by the existing journals, but their editorial boards should be ever mindful that the ultimate state of perfection in ophthalmic journalism is not yet a reality.

CLINICAL NOTES

SEPARATION AND SURVIVAL OF XIPHOPAGUS TWINS

Hyatt Reitman, M.D.
Earl E. Smith, M.D.
and
Jac S. Geller, M.D., Cleveland

Symmetrically conjoined twins are rare. Potter[1] reports only one case in the course of over 60,000 deliveries at Chicago Lying-In Hospital since 1931. Our case is the first occurring at Mount Sinai Hospital in the course of approximately 35,000 deliveries. Potter states that in all symmetrically conjoined twins, except the rare xiphopagus type in which only the lower portions of the sternum are fused, some of the viscera are shared by the two infants and surgical separation is impossible. Eastman[2] reports three authentic cases (omphalopagus type) in which surgical separation was accomplished with the survival of one twin and the death of the other. Further, he states that no case has been reported with the separation and survival of both. A survey of the literature also reveals no reported case of survival of both twins.

It is not within the province of this paper to discuss conjoined twins; the subject is well handled in Potter's "Pathology of the Fetus and the Newborn."[1] We feel, however, that this case is of interest primarily since the conjoined twins were separated and both survived.

REPORT OF CASE

A 27-year-old woman, para 1 and gravida 2, whose expected date of confinement was Jan. 15, 1953, was first seen by one of us (H. R.) when she was two months pregnant. Her previous delivery was vaginal and uncomplicated. The infant was a living boy free of anomalies.

The physical examination revealed a well-developed, well-nourished woman whose general physical condition was good and who had no complaints. The uterus was enlarged to the size of a two month pregnancy, the adnexae were clear, and the cervix was normal. Pelvic measurements were normal. The red blood cell count was 3.51 million per cubic millimeter, and the hemoglobin level 10 gm. per 100 cc. The Kline test was negative, the Rh. factor positive, and the urine free of sugar and albumin. Therapy with Mol-Iron, a hematinic containing molybdenum oxide, 3 mg., and ferrous sulfate, 195 mg., per tablet or teaspoonful, was begun and was continued throughout the pregnancy. Blood pressures and urine specimens were normal until delivery. On Sept. 4, 1952, a clinical diagnosis of a twin pregnancy was made, with both babies presenting as breeches. This was confirmed by roentgenograms made on the same date. Clinical examination on Nov. 18, 1952, revealed that one of the twins was now in a cephalic presentation. Thus, despite the fact that the twins were conjoined, twin A had rotated through an arc of 180 degrees in its spontaneous conversion from a breech to a cephalic presentation. On Dec. 11, 1952, the membranes ruptured spontaneously. The patient did not go into labor, however, and she was admitted to the hospital the next day for observation. Examination revealed the presence of two fetal hearts with

[2] Eastman, N. J.: Williams Obstetrics, ed. 10, New York, Appleton-Century-Crofts, Inc., 1950, p. 619.

engagement of the head of the first twin, the cervix 3 cm. dilated with 50% effacement. Laboratory studies showed a red blood cell count of 3.1 million and a hemoglobin level of 10.3 gm. The patient's blood was typed and cross matched. Prophylactic penicillin therapy, 300,000 units twice a day, was instituted.

On Dec. 14, 1952, at noon, approximately 48 hours after admission, the patient went into labor spontaneously. At 1:30 p. m., examination revealed the cervix to be completely dilated with the presenting part in a low occiput transverse position at 2+ station. In view of the anticipated prematurity of the infants, the patient was not given any analgesia. The patient's cervix remained completely dilated without any further descent or rotation of the infants for one hour; she was then taken to the delivery room. A spinal anesthetic that consisted of 50 mg. of procaine was administered. After that, the patient was prepared for delivery. The presenting head was rotated manually with ease, but a moderate amount of traction was required to deliver it. External rotation brought the shoulders into the anterior-posterior axis of the pelvis. Moderate traction with fundal pressure failed to deliver the shoulders for a few minutes. Suddenly, the feet of the second twin appeared at the introitus, and the possibility of conjoined twins was first entertained. A deep ether anesthetic was given in order to obtain greater relaxation of the uterus. Manual examination failed to reveal any attachment of the twins. In view of the small diameter of the fusion area, as seen after the delivery, this was understandable. Further traction with fundal pressure permitted delivery of the shoulders and chest of the first twin. At the same time, the lower extremities, pelvis, and lower abdomen of the second twin delivered, and the xiphopagus attachment was noted. Delivery of the first twin was completed and the baby placed transversely across the lower abdomen of the mother. Care was taken to avoid tearing the band of attachment between the twins. Delivery of the second twin up to the shoulders was accomplished easily, and, with the second twin's head in an occiput posterior position, the forceps were applied and the delivery completed without difficulty. The large single placenta was delivered spontaneously within five minutes, and the uterus contracted very firmly. The estimated blood loss was 200 cc. A solution, 1,000 cc. of 5% dextrose in water containing 1 cc. of oxytocin (Pitocin) together with 500 cc. of whole blood, was given intravenously. The left mediolateral episiotomy that was made at the beginning of the delivery was repaired. The postpartum course was uneventful, and the patient was discharged six days later.

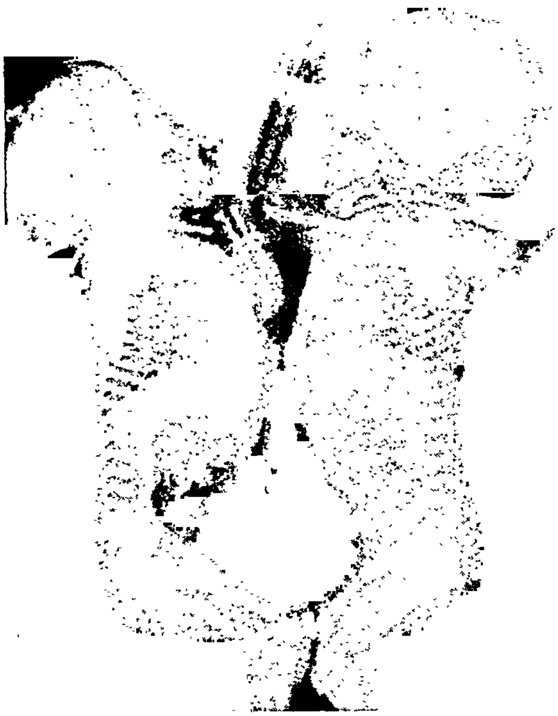

Fig. 1.—Roentgenogram of conjoined twins showing soft tissue connection, but no evidence of bony bridging, in area of inferior sternum.

Examination by one of us (E. E. S.) shortly after delivery showed twin girls one month premature joined in the region of the xiphoid process by a band of tissue measuring about 1 cm. horizontally and approximately 4 cm. vertically. Palpation of the band revealed a bridge of cartilage in its upper portion. The lower segment of the band was torn through, leaving an open laceration in the upper abdominal wall of each infant. Examination revealed two normal infants, except for the above and the fact that twin B had a loud systolic murmur heard in the region of the second left interspace parasternally. It was thought at the time to be a patent ductus arteriosus or a hemic murmur. The infants were wrapped in diapers and placed in an incubator.

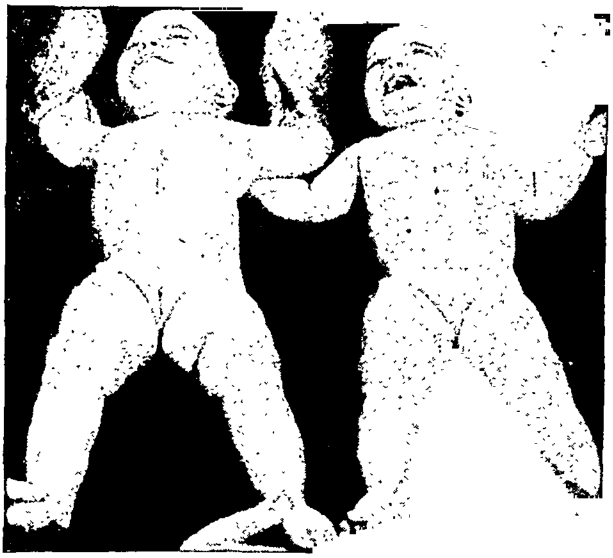

Fig. 2.—Appearance of twin girls approximately nine months after xiphopagus connection was severed.

Simultaneous electrocardiograms taken by Dr. Bernard Brofman revealed normal rates and rhythms that were asynchronous, thereby indicating separate circulatory systems. Roentgenograms revealed conjoined twins with a soft tissue connection in the region of the inferior portion of the sternum without definite evidence of bony bridging (fig. 1). Aside from this, no definite abnormalities were noted.

After the administration of vitamin K, penicillin, and streptomycin, the twins were taken to surgery. They were placed on the operating table so that twin A was on her right side and twin B on her left side. Oxygen, without anesthesia, was administered continuously throughout the entire procedure. The abdomens of both infants, as well as the connecting band, were prepared with benzalkonium (tincture of Zephiran) chloride. By sharp dissection, one of us (J. S. G.) made an incision through the skin of the band. The parietal peritoneum of twin A was visualized, but the peritoneal cavity was not entered. A few bleeders were clamped, cut, and ligated with 0000 absorbable chromic surgical sutures. The cartilaginous bridge between the two babies was severed with scissors, and the posterior skin was cut with a scalpel. This completely separated the two babies. A moist sponge was placed over the defect in the abdominal wall of twin A. The defect in twin B was repaired first. Subcutaneous tissues were brought together over the xiphoid process by means of 0000 absorbable chromic surgical sutures, and skin edges were approximated by means of 00000 silk interrupted sutures. A dry sterile dressing was applied, and the infant was taken from the operating room. The defect in twin A was repaired in a like manner. Both infants withstood the procedure well.

The infants were given nothing to eat by mouth for 18 hours and fed Karo water every 3 hours for two feedings and then a standard evaporated milk formula every 4 hours. The infants were placed in an incubator, and oxygen was given continuously for six hours postoperatively. Penicillin and streptomycin were given for three days. Twin A weighed 2,410 gm. the morning after delivery and was discharged weighing 2,520 gm. Twin B weighed 2,210 gm. the morning after delivery and was discharged weighing 2,275 gm. The murmur heard on the first day became very loud (grade 3). A questionable thrill was present. The heart was not enlarged. On the third day of life generalized cyanosis was noted, and it was evident that a congenital heart of the cyanotic type was present. At this time, an auricular septal defect or a tetralogy of Fallot was considered. The babies were discharged after 14 days. To aid the mother in the preparation of formulas liquid Similac was prescribed. At the present time, the infants are nine months of age and very well (fig. 2).

SUMMARY

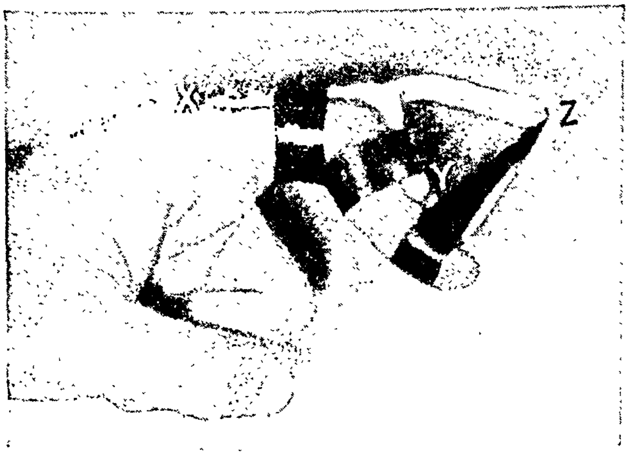
The delivery and surgical separation of xiphopagus twin girls is described. Both twins survived after being separated.

10515 Carnegie Ave. (6) (Dr. Reitman).

NEW SPLINT FOR MANAGEMENT OF MALLET FINGER

Louis Spigelman, M.D., Los Angeles

The mallet finger injury is frequently seen in general practice. The injury consists of an avulsion of the extensor tendon of a finger from its insertion, frequently with a fragment of bone, into the base of the distal phalanx. The extensor tendon of the finger divides over the back of the proximal phalanx into a central portion inserting in the base of the middle phalanx and two lateral slips that fuse together and insert on the base of the distal phalanx. When this latter insertion is torn, retraction takes place.



Splint in place (black adhesive tape used for illustrative purposes only).

Any principle of treatment for this condition must include this factor, and in treating the condition the raw area at the base of the distal phalanx must be opposed to the retracted extensor tendon. This is possible only if the distal interphalangeal joint is hyperextended while the proximal interphalangeal joint is kept at approximately 60 degrees of flexion.[1]

The difficulty of maintaining this position is well known, and a practical splint capable of maintaining this position has not been devised. Former treatment consisted of the use of a plaster of paris cast that held the terminal phalanx in hyperextension and the proximal joint at approximately 60 degrees of flexion. Anyone who has attempted to apply this type of cast realizes the difficulty of application and maintenance.

The illustrated splint (see figure) has been found to maintain the necessary position without difficulty. The splint is made easily from a strip of galvanized sheet iron or aluminum and then is padded and applied with adhesive tape.

In applying the splint, one part (*X* of the figure) is taped to the proximal phalanx. The circulation should not be restricted. The horizontal portion (*Y*), which rests against the dorsal aspect of the middle phalanx, must be extremely well padded with a strip of felt. It is important to make sure that the edge of the splint does not dig into the surface. A small pad is applied to the pulp of the distal phalanx, and then the adhesive sling is made and anchored to the upright (Z). The splint can be easily adjusted and changed, especially if the patient is told how to maintain the joints in the required position. The splint should remain in place for six weeks.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Quinine Carbacrylic Resin.—Diagnex (Squibb).—The quinine salt of a polyacrylic carboxylic acid resin containing about 1.85% of quininium ion.

Actions and Uses.—Quinine carbacrylic resin, a complex of quininium ion and carbacrylic resin, is employed as an indicator for the detection of gastric anacidity (achlorhydria) without intubation. After oral administration of the drug, the quinine in the resin is displaced by the hydrogen ions of free hydrochloric acid that may be present in the stomach. Approximately 1% of the displaced quinine is excreted in the urine within two hours following administration of the resin. A stimulant to gastric secretion is given one hour before administration of the resin. Urine voided during that hour serves as a control sample. Assay of the quinine content of urine specimens, collected at the end of the one hour control period and two hours after administration of the resin, is performed as an indication of the presence or absence of free hydrochloric acid in the stomach.

Assay of the urine for quinine is based on the measurement of its fluorescence in aqueous extract under ultraviolet light. Estimation of the urinary quinine level by this method may be carried out with a photoelectric fluorophotometer for direct calculation from a predetermined standard curve, or by visual comparison with freshly prepared standard solutions containing known amounts of quinine. If the fluorescence of the control sample corresponds to 15 mcg. or more of quinine, the entire test should be disregarded. It indicates that the patient is excreting excessive amounts of blank fluorescent materials which may result from the use of quinine or related drugs, or vitamins of the B-complex or the steroid compounds. The use of any such medication should be discontinued for one week and the test repeated. If the result from the control sample corresponds to 5 to 15 mcg. of quinine, the result from the test specimen should be corrected by subtracting the amount found in the control. If the amount in the control is less than 5 mcg., it may be ignored. The interpretation of the absence or presence of free gastric hydrochloric acid is as follows: Free gastric hydrochloric acid is absent if 15 mcg. of quinine or less is excreted in the two hour urine specimen. Free gastric hydrochloric acid is present if more than 15 mcg. of quinine is excreted in the two hour urine specimen. A range of quinine between 15 and 30 mcg. signifies a low degree of gastric acidity.

The quinine carbacrylic resin test does not furnish exact quantitative results; however, it is convenient for screening patients with minor gastric symptoms that are not considered sufficiently significant to warrant the discomfort of intubation gastric analysis or other more expensive diagnostic procedures. It should not be employed in lieu of more extensive examinations whenever these may be indicated. Until the physician has acquired experience with the resin method, doubtful results should be confirmed by repetition of the test after an interval of five to seven days. The resin test method for achlorhydria is considered useful for the diagnosis of suspected cancer of the stomach, pernicious anemia, and gastric polyps.

Quinine carbacrylic resin is of low toxicity, but it should not be given to patients with an idiosyncrasy to quinine or related drugs.

Dosage.—Quinine carbacrylic resin is administered orally as a single test dose of 2 gm. in the form of granules. Patients who are given the test should be instructed not to eat after midnight preceding the day of the test. On the morning of the test the patient should empty the bladder and discard the urine. Breakfast is withheld until the test is completed. The contents of a 0.25 gm. capsule of caffeine and sodium benzoate is stirred and taken in one-half glass of water followed by another one-half glass of water or cup of coffee or tea, without cream, milk, or sugar. One hour later or as soon thereafter as is possible, the patient voids and saves this specimen in a bottle marked "urine control." Then the 2 gm. dose of the resin is stirred well and taken in one-fourth glass of water (without chewing the granules), followed by another one-fourth glass of water. Exactly two hours after taking the resin, the urine should be voided and the entire amount saved in a bottle marked "urine sample." The bladder should be completely emptied each time; if urination ahead of the scheduled time is necessary, it should be added to that passed at the end of the designated period. After the last specimen is completed, the patient may eat breakfast. The two specimens should be delivered to a clinical laboratory as soon as it is convenient.

If desired, an injection of histamine phosphate may be used in place of oral caffeine as a stimulant to gastric secretion and the control specimen collected after a 45 minute period.

Tests and Standards.—

Physical Properties: Quinine carbacrylic resin is a buff, odorless, tasteless, free-flowing, amorphous, granular solid. It is practically insoluble in dilute acids and alkalis, alcohol, ether, and water.

Identity Tests: A 0.002% solution of anhydrous quinine hydrochloride, prepared from quinine carbacrylic resin as directed in the spectrophotometric assay for quininium ion, exhibits ultraviolet absorption maxima at about 318 and 346 mμ. [specific absorbancy, E(1%, 1 cm.), about 1501, and minima at about 270 and 325 mμ. The ratio of the absorbancies at 318 and 346 mμ. is 1.17-1.28.

Purity Tests: Dry about 1 gm. of quinine carbacrylic resin, accurately weighed, at 105° for 2 hours: the loss in weight does not exceed 5.5%.

Char about 1 gm. of quinine carbacrylic resin, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 0.2%. Save the residue for the heavy metals test.

Dissolve the residue from the ignition by heating on a steam bath with 20 ml. of water containing 2 ml. of diluted acetic acid. Run a *U. S. P. heavy metals test:* the amount of heavy metals does not exceed 20 ppm.

Assay: (Quininium Ion) Prepare a 0.002% solution of anhydrous quinine hydrochloride from quinine carbacrylic resin as follows. Transfer to a 250 ml. glass-stoppered Erlenmeyer flask about 1 gm. of quinine carbacrylic resin, accurately weighed, add 100 ml. of 0.3% hydrochloric acid, accurately measured, and shake the flask mechanically for 15 min. Centrifuge a portion of the mixture. Transfer to a second 100 ml. volumetric flask 10 ml. of the clear centrifugate, fill to the mark with 0.3% hydrochloric acid, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 346 mμ. using 0.3% hydrochloric acid as a blank. The concentration of anhydrous quinine hydrochloride in the solution in mg./ml. = absorbancy ÷ 15.0. The amount of anhydrous quinine hydrochloride is not less than 1.84 nor more than 2.25%, equivalent to not less than 1.66 nor more than 2.03% of quininium ion.

Menadione-U.S.P. (See New and Nonofficial Remedies 1953, p. 510)

Lincoln Laboratories, Inc., Decatur, Ill.

Solution Menadione in Oil with Benzyl Alcohol 2%: 15 cc. vials. A solution in sesame oil containing 2 mg. of menadione in each cubic centimeter. Preserved with 0.5% chlorobutanol.

Meth-Dia-Mer-Sulfonamides (See New and Nonofficial Remedies 1953, p. 110)

Lloyd & Dabney Company, Inc., Cincinnati.

Tablets Sulfaloid: 0.25 gm. Each tablet contains 83 mg. each of sulfadiazine, sulfamerazine, and sulfamethazine.

0.5 gm. Each tablet contains 0.167 gm. each of sulfadiazine, sulfamerazine, and sulfamethazine.

Methylbenzethonium Chloride (See New and Nonofficial Remedies 1953, p. 83)

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Methylbenzethonium Chloride: Bulk; for manufacturing use.

Naphazoline Hydrochloride-U.S.P. (See New and Nonofficial Remedies 1953, p. 200)

Ciba Pharmaceutical Products, Inc., Summit, N. J.

Solution Privine Hydrochloride 0.05%: 15 cc. nebulizers.

Phenindione (See THE JOURNAL, May 9, 1953, p. 142)

Gane's Chemical Works, Inc., Carlstadt, N. J.

Powder Phenindione: Bulk; for manufacturing use.

OVERNUTRITION AND UNDERNUTRITION

In spite of the vast amount of research in nutrition that has been carried on in recent years, little work has been done to determine the ideal plane of nutrition for different age and occupational groups. Slowly, however, bits of evidence are being fitted into place. McCance[1] has assembled some pertinent facts that are worthy of thoughtful consideration. He points out that the drive to eat and drink are essential to survival but that the control of this drive is not easily understood or, if understood, is not easily accepted and put into practice by many persons in our present civilization. Obesity has never been a problem in wild animals in their native state or in primitive man, because food was hard to obtain and it was a long time between the more lavish feasts. With the advent of modern methods of providing food, however, a certain amount of prosperity is often reflected in a tendency to overeat. The eating of only very slightly more food each day than is required to supply the energy expended will in a few years result in overweight. This and reduced activity account for the greater average weight of men of 45 as compared to those of the same height at 25 years. In the main, obesity depends on an opportunity for leisure and a plentiful supply of food. Although a sense of fulness in the stomach and the general sedation that accompanies it causes most persons to stop eating, the pleasant drowsiness induced by overeating is either consciously or unconsciously sought by certain persons with an emotional imbalance, and these are the overweight patients who are hardest to treat by dietary restrictions alone.

That the effects of obesity are serious is amply supported by the statistics of insurance companies. The obese are poor surgical risks and are predisposed to hypertension, diabetes, and atherosclerosis. It has been shown that in persons with a high serum cholesterol level atherosclerosis develops at an earlier age than in persons with normal or low levels. On the basis of this observation it was prematurely assumed in some quarters that the progress of atherosclerosis could be retarded by putting patients on a low cholesterol diet. This now appears not to be true, because both fats and cholesterol are readily synthesized in the body and neither increasing nor decreasing the cholesterol in the diet appreciably affects the serum cholesterol level. On the other hand, it is true that this level increases with age and with increases in body weight. Walker[2] has shown that, contrary to popular belief, there is a lowering of serum lipids with rapid weight loss even though liberal amounts of cholesterol are present in the diet. A nearly fat-free diet is not essential to rapid weight loss and may actually have a harmful effect on the body economy. It may be concluded then that any kind of diet that causes overweight will further atherosclerosis and that the best preventive measure is to remain at or slightly below the "ideal" weight.

Undernutrition may be due to famine, chronic debilitating disease, or to psychogenic causes associated with depression. Severely undernourished persons feel cold all the time, sleep poorly, develop a mild anemia, and as the condition progresses their skin becomes dry and scaly; they have diuresis that is increased when they assume a recumbent position, and they have diarrhea, edema, enlargement of the parotids, and gynecomastia. Severely undernourished persons at first become restless and overactive. During famines, any food that is acquired is taken home and shared with the whole family but is hidden from the neighbors. As conditions grow worse, persons no longer share with anyone else and steal from members of their own family. They may even commit murder for a crust of bread. Finally, if conditions are not relieved, complete apathy follows and death ensues.

The offspring of a mother who is undernourished resemble prematures even at full term. Undernourished children grow slowly as measured by height, weight, and "bone age." This slows their maturation and prolongs their life. Animal husbandmen have bred and fed their animals for rapid maturation. McCance believes our political husbandmen may be doing the same to our children by providing midmorning milk in school. Here it would seem that the author ignores the fact that many a listless, apparently retarded child when put on a school program of midmorning milk becomes alert and shows normal or superior intelligence. Can it be that he is placing longevity above accomplishment?

The ideal weight for a given height cannot, in the light of present knowledge, be determined categorically. It varies somewhat with the individual, his activity, age, and sex. Furthermore, most healthy persons voluntarily control their weight at the level they prefer. However, these observations and other findings require further study before many of the questions pertaining to nutrition are answered satisfactorily. Overnutrition and undernutrition constitute an almost overwhelming challenge for most of the world.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

The semiannual listing of postgraduate continuation courses for physicians, covering the period January 1 to July 15, 1954, appears elsewhere in this issue. These data, prepared as a regular service by the Council on Medical Education and Hospitals, list 1,034 courses varying in length from a few days to several months and extending to full academic years. The listing includes 539 courses offered on a full-time basis, 476 part-time courses, and 19 courses arranged to suit the convenience of the physician student. For this period, postgraduate education in some form will be offered in 35 states, the District of Columbia, and Puerto Rico. The subjects include 40 areas in the field of clinical medicine and 8 basic science subjects. There are opportunities for the physician in general practice as well as the specialist. Many courses are designed to be of assistance to physicians preparing for specialty board certification. The courses that are available for this purpose are specifically designated by a footnote. In addition, a series of courses for military personnel at medical installations are included. In a number of instances, the series is made available to civilian personnel. Notably, among the opportunities provided in this listing is a course in civilian defense.

Medical Schools, state medical societies, hospitals, graduate schools of medicine, postgraduate institutes, and state chapters of the American Academy of General Practice continue to be active in presenting this type of postgraduate education. One hundred and fifty-five agencies are participating in sponsoring the courses in this listing, including 38 medical schools, 15 hospitals, 11 graduate schools of medicine, 17 special societies, 13 state and county medical societies, 4 state health departments, 5 academies of general practice, 4 government agencies, and 1 school of public health. The remaining courses were given by liberal arts colleges, institutes, assemblies, seminars, alumni associations, foundations, and groups established for the purpose of providing postgraduate training. For many of the courses a combination of these agencies participated in sponsoring the opportunities listed. Additional contributing and sponsoring agencies are specifically indicated at the conclusion of the description of the courses.

In addition, the Council is currently engaged in the preparation of a comprehensive report on postgraduate education based on a field study throughout the country consisting of facts, figures, and opinions. A comprehensive questionnaire has recently been sent to 18,000 physicians to obtain additional data from the point of view of the physician who has taken continuation work. The Council hopes that all who have received this questionnaire will cooperate in order that this highly important aspect of its study can be adequately analyzed. Institutions and organizations offering postgraduate continuation courses for physicians are invited to announce their courses in the Council's semiannual listing.

PREVENTION OF FIREARM ACCIDENTS

Although firearms are owned and used safely by most Americans, unfortunately, through either ignorance or carelessness, many of them fail to exercise adequate precaution in their handling. Each year firearm accidents take about 2,200 lives in the United States, the death toll reaching its peak during the hunting season. The firearm fatalities among hunters are due to the discharge of guns when men carrying loaded weapons trip, stumble, or handle them carelessly while climbing over or under a fence; loading and unloading weapons; walking into the line of fire; and being mistaken for game. According to a recent study,[1] more hunters are fatally injured by the guns of their companions than by the weapons of other hunting parties, and at least four out of every five hunters reported killed by others were hit by members of their own group.

A majority of firearm deaths in and about the home, many of which occur in young children, result from the dangerous practice of playing with a gun—an "unloaded" gun frequently being pointed and fired at the victim—and from the accidental discharge of firearms while they are being cleaned, repaired, examined, or demonstrated. Some lives are lost during a scuffle for the possession of guns, while others are needlessly sacrificed as the result of a game called "Russian roulette," in which the cylinder of a gun containing but one cartridge is spun around, the participant pointing the gun at his head and pulling the trigger on the chance that it is opposite an empty chamber.

Since firearm accidents obviously represent a needless loss of life, an organized effort should be made by the people of the United States to reduce their incidence. This could be accomplished by adopting three simple measures: (1) leaving no firearms where young children can get at them; (2) not permitting inexperienced hunters to go afield without proper supervision; and (3) constantly emphasizing the necessity for caution in handling guns safely.

CONTEMPORARY OPHTHALMIC JOURNALISM

Elsewhere in this issue, Adler traces, evaluates, and speculates on the past, present, and future of ophthalmic journalism in the United States. Ever since the first American journal devoted exclusively to ophthalmology appeared in 1862, subsequent journals have been published in response either to the growth of scientific organizations or to the increasing number of physicians specializing in ophthalmology. Ophthalmic periodicals attained their numerical height at the turn of the present century, but since then the number has gradually fallen off; of 27 journals published since 1862, only 13 have survived.

How well these 13 periodicals now extant carry out their functions and obligations to ophthalmologists at large can be determined readily enough. Since no single ophthalmic journal can conceivably perform all functions equally well, it is not surprising that specialization has developed in the interests and content of the various journals in the field. In general, the functions of contemporary ophthalmic journals include such varied items as the publication of original scientific manuscripts, the description of new therapy and new instruments, the recording of new or rare disease entities, the annual review of specific topics, reviewing of books, and the publication of abstracts of current foreign and American literature, news of interest to ophthalmologists, editorial comment, correspondence to the editor, symposiums, and historical and sociological data pertaining to ophthalmology.

---

[1] Firearm Accidents Can Be Prevented, Statist. Bull. Metrop. Life Insur. Co. 34:7 (Sept.) 1953.

While these functions are, as a rule, performed in a satisfactory manner, a number of deficiencies still exist in editorial towers. Articles accepted for publication should have something to say, since the publication of articles that do not possess merit quickly damages the reputation of a journal. Another obligation of a well-edited journal is the rejection of manuscripts that are a rehash of material that has been better written before. Finally, editorial boards of specialty journals published in the United States would strengthen the cause of ophthalmic journalism by communicating frequently with one another for the purpose of analyzing ophthalmic problems that are of vital interest to ophthalmologists. Until these steps are taken, it would be well to acknowledge that perfection in ophthalmic journalism, as in other forms of journalism, is not yet an accomplished fact.

Joseph I. Greenwell, M.D.

THE ANNUAL GENERAL PRACTITIONER'S AWARD

The Board of Trustees of the American Medical Association announced at the annual Clinical Meeting in St. Louis on December 1 that Dr. Joseph I. Greenwell of New Haven, Ky., had been selected as "general practitioner of the year." Each local medical society has the right to propose a candidate to the state medical society, which in turn selects one name to be submitted to the Board of Trustees, a special committee of which chooses the recipient of the General Practitioner's Gold Medal and a citation of service to his community.

Dr. Greenwell, who is the seventh physician to be so honored, was born in Balltown, Ky., on November 27, 1873. He attended the Nelson County public schools, and received his B.A. and M.A. degrees from Cecilia College and his M.D. from the Louisville Hospital College of Medicine in 1900. For 53 years, he has practiced medicine in Nelson, Hardin, LaRue, and Marion counties, mostly within a 25-mile radius of New Haven, where his office has been throughout this period. The area in which he has practiced medicine includes Kentucky's "Lincoln country"; in fact, Lincoln was born less than 20 miles from the place where Dr. Greenwell now has his office. He has been acting health officer for Nelson County for the last eight years and is a consulting physician for the Louisville and Nashville Railroad and the Gethsemane Abbey.

Since good roads and various other conveniences have come to much of the rugged land only during the last 15 to 25 years, many of the doctor's professional chores have been under conditions almost as primitive as those which prevailed when Abraham Lincoln was born. He has answered calls by horse and buggy, on foot, by rowboat, and even by switch-engine as well as by automobile.

The use of the latest recognized scientific knowledge has been evident in all of Dr. Greenwell's professional activities. During World War II he served for four years as examining physician for the Nelson County Selective Service Board. He has rarely missed the annual scientific session of the Kentucky State Medical Association or other opportunities to keep himself informed about advances in medicine. He was in the forefront supporting the establishment of a hospital in Nelson County. Of great professional pride for Dr. Greenwell have been the nearly 4,300 babies he has delivered, of which more than 80 were born this year. Some of these deliveries took place in log cabins and some in the modern and new Flaget Memorial Hospital in Bardstown. Dr. Greenwell has been much interested in organized medicine, has been active at state, district, and county levels. Until his resignation this year, he had served for 30 years as councilor for the fourth district of the Kentucky State Medical Association. He is a past president of the Nelson County Medical and Muldraugh Hill Medical societies and a member of the American Medical Association, the Kentucky State Medical Association, and the Southern Medical Association.

Dr. Greenwell has shown his active interest in the affairs of his community by serving for 25 years as a member of the board of trustees and for 14 years as mayor of New Haven. During his administration as mayor, townspeople saw the construction of New Haven's first sidewalks, the installation of street lights, and the establishment of a public water works. He is a director and vice-president of the Bank of New Haven. With the selection this year of Dr. Greenwell, another family doctor is added to the roster of truly outstanding general practitioners.

ORGANIZATION SECTION

DR. McLESTER RECEIVES NUTRITION AWARD

The Joseph Goldberger award for outstanding contributions in the field of clinical nutrition was awarded November 28 to Dr. James Somerville McLester of Birmingham, Ala., during a meeting in St. Louis of the A. M. A. Board of Trustees. Presented by the A. M. A. through its Council on Foods and Nutrition, the annual award includes a gold medal and $1,000. Dr. McLester was cited for the outstanding role he has played in translating the results of nutrition research into human values and in the integration of nutrition into the teaching of all phases of medicine.

A practicing physician for more than 50 years, Dr. McLester now is associated with his son, Dr. James B. McLester, in the McLester Clinic, Birmingham. His book "Nutrition and Diet in Health and Disease" is widely used in the teaching of nutrition. He is professor emeritus of medicine at the Medical College of Alabama.

Dr. McLester also has been very active in medical society activities for many years. He was president of the American Medical Association in 1935 and was chairman of its Council on Foods and Nutrition. He is the fourth recipient of the award, which is made possible through grants by the Nutrition Foundation, New York. Previously, the presentation was made to Dr. Randolph West, professor of medicine, Columbia College of Physicians and Surgeons, New York; to Dr. Fuller Albright, associate professor of medicine, Harvard Medical School, Boston; and to Dr. William Henry Sebrell Jr., director, National Institutes of Health, U. S. Public Health Service, Bethesda, Md.

SCIENTIFIC EXHIBIT, SAN FRANCISCO MEETING

Plans for the Scientific Exhibit at the San Francisco Meeting are progressing rapidly. The 20 sections of the Scientific Assembly are arranging groups of exhibits dealing with their respective specialties, and there will also be several features, including cardiovascular diseases, fractures, and fresh pathology. All exhibits will be of such a nature that they will be of interest to the physician in general practice and to specialists.

The Committee on Scientific Exhibit of the Board of Trustees consists of Leonard W. Larson, M.D., Bismarck, N. D., Chairman; James R. McVay, M.D., Kansas City, Mo., and Julian P. Price, M.D., Florence, S. C. The Advisory Committee includes Harry J. Corper, M.D., Denver, James P. Leake, M.D., San Jose, Calif., Frederick P. Moersch, M.D., Rochester, Minn., Alton Ochsner, M.D., New Orleans, Howard F. Root, M.D., Boston, and Francis Scott Smyth, M.D., San Francisco. Applications for space at the San Francisco Meeting close on Jan. 18, but applications should be submitted as early as possible before that date. Application blanks may be obtained from the above committee members, from Section representatives, or from the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill.

CONFERENCE OF A. M. A. AND FARM LEADERS

Rural health problems pertaining to doctor distribution, physicians' fees, the closing of small community hospitals because of financial difficulties, and, especially, voluntary prepayment plans were discussed Sept. 30 at a dinner sponsored by the A. M. A. Council on Rural Health. The meeting, held in Chicago, was attended by 45 persons, for the purpose of exchanging ideas in the hope of solving some of the many health problems that affect rural areas. Among those attending were members of the board of directors and of the staff of the American Farm Bureau Federation, the regional directors of the Associated Women of the American Farm Bureau Federation, members of the A. M. A. Council on Rural Health, Dr. F. J. L. Blasingame, representing the A. M. A. Board of Trustees, and Dr. Bert Howard, assistant secretary.

FOUNDER'S CUP PRESENTED TO A. M. A.

The A. M. A. has come into possession of a beautiful sterling silver cup presented 52 years ago to Dr. Nathan S. Davis, who, more than anyone else, may be credited with being the founder of the A. M. A. The cup, a token of the esteem of his medical colleagues in Chicago, has been given to the A. M. A. by two of his grandchildren, Dr. Nathan S. Davis III, Chicago, and Mrs. Ruth Boissevain, widow of Dr. Charles H. Boissevain.

Inscribed on one side of the cup is the legend: "Presented to Nathan Smith Davis, A.M., M.D., LL.D., in recognition of his long and distinguished service to medicine in its every field of usefulness by the members of that profession which he has so conspicuously adorned and to whose shield he has given an added lustre. October 5, 1901." On another side is the Latin inscription: "Palman Qui Meruit Ferat"—"Let him who has won it bear the palm"—and the citation: "Pioneer in local and national organization and in graded medical instruction." On a third side is an engraved portrait of Dr. Davis, who died in 1904 at the age of 87.

NEW ASSOCIATE SECRETARY OF COUNCIL

Dr. Walter S. Wiggins, who has been assistant dean for graduate and postgraduate medical education at the State University of New York, Syracuse, since 1951, will join the A. M. A. headquarters staff Jan. 1. He is taking over the position of Associate Secretary of the A. M. A. Council on Medical Education and Hospitals, replacing Dr. Francis R. Manlove, who recently became director of the medical center and dean of the department of medicine, University of Colorado School of Medicine, Denver. Dr. Wiggins was graduated from Jefferson Medical College, Philadelphia, in 1941.

TODAY'S HEALTH WINS AWARDS

Today's Health, a monthly magazine published by the A. M. A., recently won two awards in the annual magazine show of the American Institute of Graphic Arts in New York. Ninety-two layouts were selected from some 2,000 entries for awards and exhibition. This was the first time since 1951 that *Today's Health* had entered this show, the most important magazine show in this hemisphere. It also won two awards at that time. One of the winning layouts, designed by Artist Charles Turzak, was for the article "How to Read Science Stories." Written by Patricia Jenkins, assistant managing editor of *Today's Health,* the article was published in the May issue and is being reprinted in a handbook for college science teachers.

NEW A. M. A. PUBLICATIONS

Apparatus Accepted, 1953 edition, a publication of the A. M. A.'s Council on Physical Medicine and Rehabilitation, is now available. This booklet lists and describes briefly various devices that meet the Council's standards of acceptance. Also included in the booklet are the Council's rules for submitting products and the minimum requirements for certain devices. Copies may be obtained from the Council.

New Ways to Better PR.—A digest of proceedings of the Second Medical Public Relations Institute held Sept. 2-3, 1953, in Chicago.

NEW FILM IN MOTION PICTURE LIBRARY

"School Health in Action," a sound-and-color film produced for the Oklahoma State Department of Health with the cooperation of the Oklahoma State Medical Association, has been added to the A. M. A. motion picture library. This film is the story of Waytoka, a typical city in Oklahoma—how it recognized its school health problems and through community effort launched a movement for solving these problems. The service charge for this motion picture is $2.00.

MEDICAL NEWS

CONNECTICUT

Howe Award to Dr. Wilson.—The American School Health Association recently cited Dr. Charles C. Wilson, professor of education and public health at Yale University, New Haven, as a "distinguished contributor to the health of school children" and bestowed on him the William A. Howe award. Dr. Wilson, a former president of the American School Health Association, was editor of "Health Education," a report of a Joint Committee on Health Problems and Education set up by the National Education Association and the American Medical Association. He is the author of health texts for both elementary and secondary schools. Last spring he received the medal of the City of Paris for his contribution in the formation of the International Union for Health Education of the Public. He is president of the Connecticut Health League and former president of the Connecticut Tuberculosis Association. Dr. Wilson served as director of the department of health and physical education in the public school system of Evansville, Ind., from 1928 to 1934, and in the schools of Hartford from 1934 to 1941, when he was appointed professor of health and physical education at the Teachers College of Columbia University. He has been a member of the Yale faculty since 1946.

ILLINOIS

Trucking Industry Fellowships.—The Illinois Trucking Industry in observance of its 50th anniversary announces the establishment of two $5,000 fellowships for further study of mentally retarded children. The fellows will be chosen from graduates of medical schools in the midwest. Final selection will be made by a committee composed of Dr. Karl Meyer, chief of staff at Cook County Hospital, Chicago; Dr. John Bigler, head, department of pediatrics, Northwestern University Medical School; Dr. Samuel Hoffman, director of Hektoen Institute for Medical Research; Dr. Abraham Levinson, director, Dr. Julian D. Levinson Research Foundation at the institute; Ted Baker, president, Central Motor Freight Association of Chicago; and Walter Mullady, past president, American Trucking Association. The fund will pay each fellow $5,000 during the year-long training period and an additional $5,000 to cover other costs in connection with the study period. The work will be done under Dr. Levinson.

Chicago

Society News.—At the meeting of the Illinois chapter of the American College of Chest Physicians, Chicago, Dec. 11, Dr. John B. Schwedel, assistant clinical professor of medicine, Columbia University College of Physicians and Surgeons, New York, presented "Roentgenology of the Normal and the Abnormal Heart."——The Chicago Heart Association and the Society of Internal Medicine will hold a joint meeting Dec. 14, 8 p. m., at the Drake Hotel. The following program will be presented:

Isolation and Characterization of the Mammalian Striated Myofibrils, Arnold Brown and George M. Hass.
Pathological Changes in Congestive Heart Failure, Oglesby Paul, Gordon F. Vawter, Albert W. Schweitzer, Armin F. Schick, and George M. Hass.
Experimental Atherosclerosis (Recent Advances), Richard Jones.

Dr. Edith Potter Honored.—Dr. Edith L. Potter, associate professor of pathology at the University of Chicago, was awarded the honorary degree of doctora honoris causa by the University of Brazil at Rio de Janeiro, Oct. 1, at the dedication of the Instituto de Puericultura, the University's new hospital for children under 2 years of age. Dr. Potter was invited to set up the pathology laboratory of the institute when it was under construction in 1949. She received an award of achievement in 1951 from the University of Minnesota, Minneapolis, for research in the causes of infant death and the Rh factor and last year received the Elizabeth Blackwell award of the New York Infirmary. Author of "Pathology of the Fetus and the Newborn," Dr. Potter is a consultant to the Armed Forces Institute of Pathology, Washington, D. C., and the Chicago Health Department. She is a past president of the Chicago Pathological Society.

University News.—The University of Illinois College of Medicine announces that Drs. Louis Lams and Raymond E. Robertson have received nonsalaried appointments as clinical assistant professors of psychiatry and that Dr. M. Jeanne Spurlock will serve in the same capacity on four-fifths time. Dr. Lams will assist in the teaching program of residents and senior clerks. Dr. Robertson recently was appointed acting superintendent of the Institute for Juvenile Research, replacing Dr. Julius B. Richmond who resigned. Dr. Spurlock will work as a child psychiatrist on the children's psychosomatic ward and will assist in the teaching of medical students, residents, and ancillary personnel.——Dr. Frank J. Fara, professor of obstetrics, Cook County Graduate School of Medicine, has been appointed clinical assistant professor on the nonsalaried staff of the department of obstetrics and gynecology at the University of Illinois College of Medicine. Dr. Fara, who was associated with Northwestern University Medical School, is a member of the attending staff at Cook County Hospital, and head of the department of obstetrics and gynecology at the Hospital of St. Anthony de Padua.

KANSAS

University News.—Dr. Mahlon H. Delp, professor of medicine, was elected by the recently graduated senior class of the University of Kansas School of Medicine, Kansas City, as the faculty member who in their opinion had been most devoted to his primary objective as a teacher.

Awards to Seniors and Residents.—At the annual medical staff night of the department of medicine, University of Kansas School of Medicine, Kansas City, to honor visiting staff physicians, medical students, and residents the following awards were presented:

A clock with an engraved brass plaque inset to Dr. Jesse D. Rising as the visiting physician who had spent the greatest amount of time in the senior medicine outpatient clinic during the previous five months.
The Porter award of $300 to Lamont Gaston, graduating senior, Lawrence, for the best four year grade average in medical school.
The Marcell award of a medicine bag and $100 to graduating senior Dale Griswold, Newton, for the highest total grades on the junior and senior comprehensive written examinations in medicine.
The Marcell award of $100 to Floyd W. Baker, Leavenworth, the graduating senior making the greatest improvement between the junior and senior years in medicine.
The Guffey prize of $100 for the graduating senior doing the best work in the department of obstetrics and gynecology, to Donald N. Kuenzi, Helena, Mo.
The Guffey prize of $250 to K.U.M.C. resident or intern doing the best work in the department of obstetrics and gynecology, to Dr. William J. Spanos, St. Louis.
The Ginsburg award of $100 for the outstanding record in the sophomore physical diagnosis course, to Daniel Lester Azarnoff, Lawrence.

KENTUCKY

State Medical Election.—At the annual meeting of the Kentucky State Medical Association in Louisville, Dr. J. Duffy Hancock, Louisville, assumed the presidency, and Dr. Clyde C. Sparks, Ashland, was chosen president-elect.

Posthumous Award to Dr. Barr.—For the first time in Kentucky State Medical Association history, the distinguished service medal of the association was conferred on a deceased

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

member (Dr. R. Haynes Barr, Owensboro, who died May 5, while serving as president of the association). Dr. E. Bruce Underwood, Louisville, secretary, presented the award to Mrs. Barr at the annual dinner, Sept. 24.

MARYLAND

Dr. Follis Goes to Utah.—Dr. Richard H. Follis Jr., formerly associate professor of pathology at Johns Hopkins University School of Medicine, Baltimore, has been appointed professor and head of the department of pathology at the University of Utah College of Medicine, Salt Lake City. He will serve also as pathologist to the Salt Lake County General Hospital and as consultant in pathology to the Veterans Administration hospitals in Salt Lake City.

Symposium on Tuberculosis.—At the annual meeting of the Baltimore City Medical Society, Dec. 18, Dr. Ross L. McLean, Baltimore, will serve as moderator for a symposium on tuberculosis, with the following participants: Col. Carl W. Tempel (MC), chief, medical service, Fitzsimons Army Hospital, Denver; Dr. J. Maxwell Chamberlain, associate professor of surgery, Columbia University College of Physicians and Surgeons, New York; Mr. William Steenken Jr., Trudeau Laboratory, Trudeau, N. Y.; and Dr. Oscar Auerbach, chief, laboratory service, Veterans Administration Hospital, East Orange, N. J.

MINNESOTA

Dr. Krusen Honored.—Dr. Frank Hammond Krusen, head of the section on physical medicine, Mayo Clinic, Rochester, since 1935 and professor of medicine, Mayo Foundation, who recently received from Gov. C. Elmer Anderson the state's award of merit for his contributions to employment through rehabilitation of physically handicapped persons, has been named to receive the second annual physician's award by the President's Committee on Employment of the Physically Handicapped. Chairman of the A. M. A. Council on Physical Medicine and Rehabilitation, a past president of the American Congress of Physical Medicine, and councilor of the National Association for Crippled Children since 1947, Dr. Krusen serves on the advisory board of the Minnesota Rehabilitation Association and is the author of books and articles in the field of physical medicine. In 1944 he was chairman of the Baruch Committee on War and Post-War Physical Rehabilitation. The award will be presented during the annual meeting of the Congress on Industrial Health at Louisville, Feb. 23-24, 1954.

MONTANA

State Medical Election.—At the annual meeting of the Montana Medical Association in Billings, Dr. Sidney C. Pratt, Miles City, was elected president, Dr. John J. Malee, Anaconda, president-elect, Dr. George W. Setzer, Malta, vice-president, Dr. Theodore R. Vye, Billings, secretary-treasurer, Dr. Park W. Willis Jr., Hamilton, assistant secretary-treasurer, and Drs. James M. Flinn, Helena, and Francis L. McPhail, Great Falls, executive committee members.

Personal.—Dr. Maurice A. Shillington, a past president of the Montana Medical Association, has been elected to honorary membership in the association. Dr. Shillington recently retired from the active practice of medicine in Glendive and moved to Minnesota.——Dr. Stuart O. Olson, Glendive, was recently appointed a member of the state board of medical examiners and a member of the governor's committee on mental health to succeed Dr. Shillington, who resigned on retirement.——Dr. William F. Morrison, Missoula, has been appointed to the state board of health to succeed Dr. Edward S. Murphy, Missoula, who resigned.

Memorial Carillon.—Dr. William F. Cogswell, Helena, executive officer and secretary of the state board of health from 1912 to 1946, was honored in October at the dedication of the 47-bell memorial carillon in a tower on the campus of Montana State University, Missoula, when a carillon bell was dedicated in his name in recognition of 34 years of public health service to Montana. The Cogswell bell plaque at the base of the tower reads: "Presented by William O. Cogswell '23, Edward B. Cogswell, and Andrew C. Cogswell '27 in honor of their father, Dr. William F. Cogswell, pioneer in Montana public health and secretary of the State Board of Health 1912-1946."

NEW YORK

Warning Against Obsolete Refrigerators.—The state health department has issued a warning that a number of obsolete water-cooled gas refrigerators that had been condemned for use in New York City have been sold or transferred for installation in apartment houses located outside the city limits. About 50,000 of the water-cooled gas refrigerators in New York City have already been abandoned. In all, there were about 200,000 of the appliances in the city, all 25 or more years old. The department also warned that a considerable number of deaths occur each year throughout the country because of fumes from improperly adjusted gas burners operating in poorly ventilated rooms.

The 192 Million Dollar Hospital Program.—With the breaking of ground for the 552-bed Coney Island Municipal Hospital, all large projects of the 192 million dollar postwar program of the city department of hospitals will be either under construction or already operating. The latter group includes the 1,920-bed Bird S. Coler Memorial Hospital and Home on Welfare Island (20 million dollars); the Tuberculosis Hospital of the Kings County Hospital Center, a 716-bed unit (8 million dollars); the James Ewing Hospital, a 275-bed cancer unit affiliated with Memorial Center for Cancer and Allied Diseases (6 million dollars); and the Francis Delafield Hospital, a 307-bed cancer facility affiliated with Columbia-Presbyterian Medical Center (9 million dollars). Nearing completion and scheduled for opening within the next year are a 236-bed addition to Queens General Hospital, Jamaica (6 million dollars) and the 511-bed Nathan B. Van Etten Hospital, a tuberculosis unit of the new Bronx Municipal Hospital Center (approximately 15 million dollars). Under construction are the Abraham Jacobi Hospital, an 898-bed general care unit of the Bronx Municipal Hospital Center, which, with the auxiliary buildings of the center, will cost 23 million dollars; the 1,050-bed East Harlem General Hospital (replacement of the old Metropolitan Hospital on Welfare Island), which will cost 26 million dollars; the 961-bed Elmhurst General Hospital (replacement of the old New York City Hospital on Welfare Island), which will cost 26 million dollars; and the new Bellevue Nurses' Residence and School, which will accommodate 900 nurses and student nurses, and cost 15 million dollars. The remainder of the 192 million dollars is being spent on a program of modernization of existing facilities. The new Coney Island Municipal Hospital, a 10-story building, which will occupy a 10-acre site adjacent to the present hospital, will be a general hospital but will provide tuberculosis and contagious disease services. The present Coney Island, constructed in 1910, will be converted into a 279-bed facility to care for the chronically ill. When all construction is completed, the hospital will have a total capacity of 831 beds and a new outpatient department designed to accommodate more than 600 clinic patients daily. The 15 million dollar cost includes renovation of the present hospital. Among the speakers at the ground-breaking were Drs. John E. Hammett, president of the medical board of the hospital, and Louis Berger, president of the Medical Society of the County of Kings. Dr. Marcus D. Kogel, commissioner of hospitals, presided.

New York City

Tumor Clinic.—Dr. Herbert C. Maier, director of surgery, Lenox Hill Hospital, will present "Cancer of the Lung" at the tumor clinic conference at Harlem Hospital (Women's Pavilion, Main Floor, 137th St. Entrance), Dec. 16, 10:45 a. m.

Harvey Lecture.—Dr. Paul Klemperer, professor of pathology, Columbia University College of Physicians and Surgeons, will deliver the fourth Harvey lecture, "The Significance of the Intermediate Substances of the Connective Tissue in Human Disease," of the 1953-1954 series at the New York Academy of Medicine, Dec. 17.

Geriatric Clinic.—A clinic specializing in the ills of the aged was recently dedicated at Beth Israel Hospital, 17th St. near 1st Ave. The clinic is named after Mr. Charles H. Silver, now serving his sixth consecutive term as president of the hospital. Hon. Alben W. Barkley dedicated the six story granite and brick structure. Msgr. James J. Lynch, director of Catholic Charities, who represented Francis Cardinal Spellman, gave a $10,000 check from the Alfred E. Smith Memorial Foundation, and Mayor Impellitteri reviewed the history of Beth Israel since its establishment by a group of immigrants 63 years ago.

Dr. Jaffee Honored.—Dr. Henry L. Jaffe, director of laboratories, Hospital for Joint Diseases, who recently conducted clinicopathologic conferences on skeletal diseases, sponsored by the British Post-Graduate Medical Federation (University of London) and the Institute of Orthopaedics of London, was made an honorary member of the Royal Society of Medicine. He also delivered a Lord Moynihan lecture before the Royal College of Surgeons and conducted a clinicopathologic conference at the Royal National Orthopaedic Hospital, and at Oxford he lectured at the Nuffield Orthopaedic Center. His tour included Manchester, Liverpool, and Glasgow, where he conducted a clinicopathologic conference at the teaching hospitals connected with the medical schools. The tour terminated in Belfast, Ireland, where he held a slide seminar before the Pathologic Society of Great Britain and Ireland.

NORTH CAROLINA

Personal.—Dr. Calvin C. Applewhite, Raleigh, director of the State Board of Health's Division of Local Health Administration, was honored by the North Carolina Public Health Association at its annual meeting at Nags Head, when he received the Carl V. Reynolds award for distinguished service in the field of public health.

Society-University Project.—A new type of medical continuation education project was recently inaugurated through a cooperative program sponsored by the Rowan-Davie Counties Medical Society and the University of North Carolina School of Medicine, Chapel Hill. Under the plan a member of the staff of the medical school selected by the program committee of the society will visit the Rowan Memorial Hospital, Salisbury, once a month to participate in locally planned medical activities. He will take part in such activities as consultations, clinical conferences, rounds, and reviews of deaths and will give an informal discussion on some selected topic. This type of postgraduate program, related to the local problems and situation, involves extensive participation by local physicians.

OHIO

Dr. Goldblatt Returns to Cleveland.—Dr. Harry Goldblatt, who in 1946 left Cleveland to develop and direct the Institute for Medical Research at the Cedars of Lebanon Hospital, Los Angeles, has returned as director of laboratories at Mount Sinai Hospital. During the past seven years Dr. Goldblatt has conducted investigations into the humoral mechanisms of the production of high blood pressure, has continued the experimental studies of liver disease which were initiated some 15 years ago in Cleveland in cooperation with Dr. Paul Gyorgy, Philadelphia, and has furthered the studies on the experimental production of cancer, originally undertaken in 1930 at the Institute of Pathology of Western Reserve University School of Medicine, Cleveland. Dr. Goldblatt has been affiliated with the Lakeside Hospital, Cleveland, Lister Institute of Preventive Medicine, London, England, the University of Colorado School of Medicine, Denver, Western Reserve University School of Medicine, Cleveland, and the University of Southern California School of Medicine, Los Angeles. He is the recipient of the John Phillips award, the Alvarenga award, the annual scientific award of Phi Lambda Kappa, the Ward Burdick award, the New Orleans trophy by Zeta Beta Tau, the Charles Eiseman award, and the Charles Mickle fellowship award. During World War I he served as a lieutenant in the medical corps.

OKLAHOMA

Society News.—The Oklahoma Society of Psychiatrists and Neurologists has elected Dr. Alfred A. Hellams, Oklahoma City, president, Dr. Harry Wilkins, Oklahoma City, vice-president, Dr. Charles A. Smith, Oklahoma City, secretary-treasurer, and Dr. Neil B. Kimerer, Oklahoma City, member of the executive committee.

Mental Health Board.—Pursuant to repeal of the old mental health law and enactment of a new one providing for appointment of a board of mental health composed of two physicians, one attorney, and three lay persons, Gov. Johnston Murray has appointed Drs. Maude M. Masterson, Oklahoma City, and Joe E. Tyler, Tulsa, to represent the medical profession. The appointments were made from a list of names submitted by the council of the Oklahoma State Medical Association.

Fifty Year Club.—Dr. Charles E. Calhoun, Sand Springs, recently received a gold pin commemorating the completion of 50 years in the active practice of medicine. The presentation was made by Dr. John E. McDonald, Tulsa, president of the Oklahoma State Medical Association. Dr. Calhoun practiced at Shawnee for several years, in 1910 moved to Sand Springs, and during World War I served as an officer in the U. S. Army Medical Corps.——Lifetime membership and a service recognition plaque in recognition of more than 50 years of medical service were recently presented to Dr. John L. Lehew, Pawnee, in a ceremony attended by Dr. Lehew's three sons, Dr. Elton W. Lehew and Dr. John L. Lehew Jr., Guthrie, and Clifford H. Lehew, D.D.S., Pawnee.——The Tillman County Medical Association recently bestowed on Dr. George A. Comp, Manitou, a 50 year gold pin. Dr. Comp, who after graduation joined his father, a physician and surgeon in Edmond, Okla., came to Manitou in 1906. He was recently honored by Manitou citizens by being named the community's most useful citizen.

TENNESSEE

University News.—Dr. Elmer E. Pautler, formerly an instructor of pathology at the Bowman Gray School of Medicine, Winston-Salem, N. C., has joined the staff of the University of Tennessee Medical Units, Memphis, as assistant professor of pathology and bacteriology.——Dr. Conley Hall Sanford, who has been affiliated with the University of Tennessee College of Medicine, Memphis, since 1920, and since 1939 has been chief of its division of medicine and chief of staff of the John Gaston Hospital, has retired from these positions but will continue as professor of medicine and as a private practitioner. Dr. Sanford is a charter member of the local chapter of Alpha Omega Alpha and of the American Board of Internal Medicine.——Dr. Phillip C. Schreier has been appointed acting chief of the division of obstetrics and gynecology, University of Tennessee College of Medicine and the John Gaston Hospital, Memphis, to replace Dr. Frank E. Whitacre, who recently resigned to join the staff of Vanderbilt University College of Medicine, Nashville.

Craig-Brown Memorial Fund Perpetuated.—Classmates of Drs. William Riney Craig and Clyde Hulee Brown, who lost their lives in World War II, will be listed perpetually among the annual contributors to the living endowment of Vanderbilt University, Nashville. Dr. Craig, who died on a Japanese prison ship in January, 1945, was commissioned a medical officer in the regular U. S. Army on graduation, was chief of the surgical service at Sternberg General Hospital in Manila at the time of the Japanese attack, and was executive officer of a hospital on Bataan until captured and imprisoned at Cabanatuan, where he served as medical officer for his fellow prisoners for 2½ years. Dr. Brown, who was killed by an aerial bomb April 12, 1945, had practiced as a specialist in internal medicine in New York City from 1928 until 1941, when he was commissioned in the Naval Reserve. At the time of his death he was the commander in charge of a mobile hospital unit attached to the Third Amphibious Corps, U. S. Marines, on Okinawa. The original purpose of the scholarship fund created by their classmates for the education of Dr. Craig's daughter and Dr. Brown's son having been fulfilled, the creators of the fund have changed its name to the William Riney Craig and Clyde Hulce Brown memorial fund, increased its amount in order to qualify as a permanent interest-paying fund in Vanderbilt's endowment, and directed that the annual income henceforth be credited to the living endowment.

VERMONT

Fifty Year Club.—The following physicians were recently elected to the 50 Year Club of the Vermont State Medical Society: Edwin A. Colton, Montpelier; Charles F. Dalton, Burlington; Albert C. Eastman, Woodstock; Fred A. Edmunds, Bethel; and Thomas J. Hagan, Springfield.

VIRGINIA

University News.—Dr. Edwin P. Lehman, chairman of the department of surgery and gynecology, has retired after 25 years as a faculty member of the University of Virginia School of Medicine, Charlottesville.

Personal.—Dr. Ralph G. Beachley, director of public health in Arlington County, was recently elected president of the Metropolitan-Washington Tuberculosis Conference, a group sponsored by the tuberculosis associations of the District of Columbia, Maryland, and Virginia.——Dr. Arnold F. Strauss, pathologist of De Paul Hospital, Norfolk, was honored during his recent visit to Peru by being made a corresponding member of the Peruvian Society for Pathology.

ALASKA

Heart Association Organized.—After the visit to Alaska this summer of Mr. Robert V. Titus, regional director of the American Heart Association, Inc., district chapters of the voluntary agency were organized in Fairbanks, Anchorage, Juneau, and Ketchikan. It is proposed that the executive committees of the four districts will serve as the territorial agency of the organization.

Accidents Chief Cause of Death.—Accidents were the chief cause of death in Alaska in 1952 for the second successive year. Accidents of all types accounted for 20.8%, or 262 of the 1,261 deaths in the territory last year, according to provisional data received by the Bureau of Vital Statistics. Heart diseases were in second place, causing 217 deaths, or 17.2%. Tuberculosis took the third highest toll of lives, causing 13.6%, or 172 of the total deaths. Though the 1952 data are still considered provisional, no change in the order of the final figures for the year is anticipated, according to the director of the Bureau of Vital Statistics, who said there are some known airplane accident deaths not yet officially reported which will later raise the total death by accident figure. Indication of a drop in the tuberculosis deaths in Alaska is attributed to the intensive tuberculosis control work during the past six years, in which cases were found earlier and more hospital beds were available.

GENERAL

National Society for the Prevention of Blindness.—This organization will hold its membership meeting Dec. 17, 4 p. m., in the Waldorf-Astoria Hotel, New York. The speaker will be Dr. Arnall Patz, research assistant in ophthalmology, Georgetown University School of Medicine, Washington, D. C., whose subject will be "Retrolental Fibroplasia." The society will hold its annual meeting in St. Louis, at the Hotel Jefferson, March 10-12, 1954.

Sedgwick Memorial Award.—At its annual meeting in New York the American Public Health Association presented its highest annual award, the Sedgwick memorial medal for distinguished service in public health to Carl E. Buck, Dr.P.H., professor of public health practice at the University of Michigan School of Public Health, Ann Arbor. Dr. Buck, a member of the Typhus Fever Commission to the Balkans in 1915 and 1916, served in the U. S. Army Air Service during World War I and later became a member of the staff of the International Health Board of the Rockefeller Foundation, doing malaria work in the southern states.

Trudeau Society Invites Papers.—The American Trudeau Society invites submission of papers for the 1954 annual meeting, Atlantic City, N. J., May 17-21. Abstracts in duplicate must be sent before Jan. 1, 1954, to Dr. Julius L. Wilson, chairman of the Medical Sessions Committee, Henry Phipps Institute, 7th and Lombard Sts., Philadelphia 47. Abstracts should be limited to a 300 word summary including important data and conclusions. Subjects for presentation may include all scientific aspects of tuberculosis and nontuberculous respiratory and cardiopulmonary disease as well as the results of investigative work bearing on these subjects.

Pediatric Residency Fellowships.—The American Academy of Pediatrics will grant 12 or more fellowships for pediatric residents for a period of six months to one year. These fellowships, created to enable young physicians in financial need to complete their pediatric training, carry a stipend of $500-$1,000. The fellowships, made possible by a grant to the academy from Mead Johnson & Company, will be granted as of July 1, 1954. Deadline for receipt of applications will be March 1. Further information may be had from Dr. James G. Hughes, Le Bonheur Children's Hospital, Adams and Dunlap, Memphis 5, or the American Academy of Pediatrics, 610 Church St., Evanston, Ill.

Dr. Mountin Memorial Volume.—A national committee is sponsoring the publication of a memorial volume of the writings of the late Dr. Joseph W. Mountin, "intended to reflect Dr. Mountin's diversity of interests, breadth of vision, and the pioneering nature of his work in many of the branches of public health work" and to serve "as a basic document for students and practitioners in public health." Dr. Leonard A. Scheele, Surgeon General, U. S. Public Health Service, is honorary chairman of the committee. Dr. Thomas Parran, Pittsburgh, and Dr. Joseph O. Dean, Washington, D. C., are co-chairmen, and C. Mayhew Derryberry, Ph.D., Washington, D. C., is serving as executive secretary. Information may be secured from and contributions sent to Joseph W. Mountin Memorial, P. O. Box 1610, Washington, D. C.

Libraries Association Translations Pool.—The Special Libraries Association, in cooperation with the John Crerar Library, Chicago, has created a new translations service in recognition of the increasing need for information regarding existing translations and for the availability of inexpensive copies. The association has deposited in the Crerar library, 1,300 translations which form the nucleus of the pool. Because the usefulness of the pool will be in direct proportion to the number of translations available, contributions of good copies of complete translations are solicited from government agencies, technical societies, universities, industries, and individuals. If copies are not available for deposit, they may be loaned to the Crerar library for a short time, with permission to microfilm or, alternatively, a 35 mm. microfilm may be deposited. Permission to lend or to reproduce in photocopy is a condition of deposit. Photoprint or microfilm copies of the translations listed may be obtained at the regular rates charged by the Crerar library. Currently, these rates are $1.40 for 10 pages or fraction thereof of photoprint, or 50 pages or fraction thereof of microfilm, plus a service charge of $1 for each translation (payable in advance). Discounts of 3.5-14% are allowed on advance purchase of photoduplication coupons. A price list will be sent on request.

Society News.—At the annual meeting of the **American Society of Anesthesiologists** in Seattle, Dr. Brant B. Sankey, Cleveland, was selected as president-elect, and Drs. Daniel C. Moore, Seattle, and Paul H. Lorhan, Kansas City, Kan., were elected as first and second vice-presidents. Dr. J. Earl

Remlinger Jr., Evanston, Ill., and Dr. Moses H. Krakow, New York, were reelected secretary and treasurer, respectively.—— **The American Academy of Ophthalmology and Otolaryngology** announces that, by special action of the council voted by mail, Dr. Walter H. Theobald, Chicago, president-elect, has been named to succeed the late Dr. John J. Shea, Memphis, who, elected at the 1952 annual meeting, died a few weeks later. Dr. Algernon B. Reese, New York, who was chosen president-elect of the academy at the annual meeting in Chicago, will assume the presidency in January, 1955. Other officers elected at the meeting include Drs. Francis H. Adler, Philadelphia, Theodore E. Walsh, St. Louis, and Dohrmann K. Pischel, San Francisco, vice-presidents, Dr. Lawrence R. Boies, Minneapolis, secretary for otolaryngology, Dr. Kenneth L. Roper, Chicago, secretary for ophthalmology, Dr. Albert D. Ruedemann, Detroit, secretary for instruction in ophthalmology, Dr. Dean M. Lierle, Iowa City, secretary for instruction in otolaryngology and maxillofacial surgery, Dr. Erling W. Hansen, secretary for public relations, and Dr. Daniel Snydacker, Chicago, secretary for home study courses.

FOREIGN

Meeting on Rheumatology.—The Rome Center of Rheumatology and the Italian Society of Rheumatology announce that the second Roman Rheumatological Days will be held in Rome, Feb. 13-14, 1954. Those wishing to submit reports must send the title of the paper no later than Dec. 31 to the Segreteria della Giornata, % Instituto di Semeiotica Medica, Universitá di Roma, and must submit a 10 line, typewritten abstract of the report no later than Jan. 15.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Federation for Clinical Research:

- Eastern Section, Amphitheater, Children's Medical Center, Boston, Jan. 4. Dr. Walter Judson, Evans Memorial Hospital, Boston, Chairman.
- Southern Section, Jung Hotel, New Orleans, Jan. 29. Dr. William Parson, University of Virginia School of Medicine, Charlottesville, Va., Chairman.
- Western Section, Auditorium, University of Oregon Medical School, Portland, Ore., Jan. 28. Dr. I. S. Edelman, University of California Medical Center, San Francisco Hospital, San Francisco 15, Secretary.

American Laryngological, Rhinological and Otological Society:

- Eastern Section, Waldorf-Astoria, New York, Jan. 8. Dr. Francis W. Davison, Danville, Pa., Chairman.
- Middle Section, Park Plaza Hotel, St. Louis, Jan. 18. Dr. Ralph J. McQuiston, 20 North Meridian St., Indianapolis 4, Chairman.
- Southern Section, Brown Hotel, Louisville, Ky., Jan. 16. Dr. Lester A. Brown, 490 Peachtree St., N.E., Atlanta 3, Ga., Chairman.

American Society for Surgery of the Hand, Palmer House, Chicago, Jan. 22. Dr. George V. Webster, 960 East Green St., Pasadena 1, Calif., Secretary.

Northwest Society for Clinical Research, Portland, Ore., Jan. 28. Dr. Arthur L. Rogers, 1216 S.W. Yamhill St., Portland, Ore., Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Eastern Pennsylvania, Philadelphia, Jan. 15. Dr. Thomas M. McMillan, 330 S. Ninth St., Philadelphia 7, Governor.

Western Society for Clinical Research, Portland, Ore., Jan. 29-30. Dr. Herbert N. Hultgren, Stanford Hospital, San Francisco 15, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

French Medical Congress of French Speaking Countries in the Caribbean, Port-au-Prince, Haiti, Dec. 15-21. For information write: Dr. Constant Pierre-Louis, School of Medicine, Port-au-Prince, Haiti.

Health Congress of the Royal Sanitary Institute, Scarborough, England, April 27-30. Mr. P. Arthur Wells, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1, England, Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress on Child Psychiatry, University of Toronto, Toronto, Ontario, Canada, Aug. 13-14, 1954. Miss Helen Speyer, International Association for Child Psychiatry, 1790 Broadway, New York 19, New York, U. S. A., Executive Officer.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Diseases of the Chest, Barcelona, Spain, Oct. 4-8, 1954 Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, Executive Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6e, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Colorado:* *Examination.* Denver, Dec. 15-16. Final date for filing application was Nov. 14. *Endorsement.* Denver, Jan. 12. Final date for filing application is Dec. 12. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Dec. 14. Sec., Dr. Daniel L. Seckinger, 1740 Massachusetts Ave., N.W., Washington.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Hawaii: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Jan. 26-28. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 16-18. Exec. Sec., Miss Ruth V. Kirk, 538 K of P Bldg., Indianapolis.

Massachusetts: *Examination.* Boston, Jan. 12-15. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Michigan:* *Examination.* Detroit and Ann Arbor, June 1954. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Montana: *Reciprocity.* Helena, April 5. *Examination.* Helena, April 6-7. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity.* Reno, Jan. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, March 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* *Examination and Reciprocity.* Santa Fe, April 12-13. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, Syracuse and New York City, Feb. 16-19. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Winston-Salem, Jan. 18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, Jan. 4-5. *Reciprocity.* Portland, Jan. 14-16. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Jan. 7-8. Admin. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Dec. 16-17. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Vermont: *Examination.* Burlington, Feb. 1954. Sec., Dr. F. J. Lawliss, Richford.

Washington:* *Examination.* Seattle, Jan. 10-13. *Reciprocity.* Seattle, Jan. 10. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: *Examination and Reciprocity.* Charleston, Jan. 11-13. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: *Oral Examination and Reciprocity.* Cheyenne, Feb. 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Dec. 15. Sec., Mr. H. D. Rhodes, University of Arizona, Tucson.

Connecticut: *Examination.* New Haven, Feb. 13. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

Iowa: *Examination.* Des Moines, Jan. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, Feb. 12-13. Sec., Mrs. Anne Baker, 410 W. Allegan St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Jan. 5-6. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Minneapolis 14.

Nevada: *Examination.* Reno, Jan. 5. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

New Mexico: *Examination.* Santa Fe, Jan. 17. Sec., Miss Marguerite K. Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, March 6, June 5, Sept. 11 and Dec. 4. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Tennessee: *Examination.* Memphis, Dec. 30-31. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* April 1954. Location determined by number of applicants from different sections of the state. Sec., Brother Raphael Wilson, C.S.C., 407 Perry-Brooke Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 6-7. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

Wisconsin: *Examination.* Madison, April 3. Final date for filing application is March 26. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

*Basic Science Certificate required.

DEATHS

Dillehunt, Richard Benjamin ⊕ Portland, Ore.; born in Decatur, Ill., July 12, 1886; Rush Medical College, Chicago, 1910; dean emeritus at the University of Oregon Medical School, where he was professor of anatomy and assistant dean from 1912 to 1917, dean from 1920 to 1943, and also clinical professor of orthopedic surgery and head of the department; the faculty of the University of Oregon Medical School gave a dinner July 10, 1941, honoring him on his 30th anniversary as a member of the school, and on this occasion a portrait of him was unveiled; specialist certified by the American Board of Orthopaedic Surgery; served as orthopedic surgeon to Base Hospital No. 46 of the American Expeditionary Forces during World War I; honorary member of the Oregon State Medical Society; member of the American Orthopaedic Association, Pacific Coast Surgical Association of which he was president, 1939-1940, North Pacific Surgical Association, and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; first surgeon-in-chief of the Shriners' Hospital for Crippled Children, which he helped to establish; chief of staff of the Portland Free Dispensary, the forerunner of the present Outpatient Clinic; chief of orthopedic service for Doernbecher Memorial Hospital for Children; consulting orthopedic surgeon to Veterans Administration Hospital and to the State Industrial Accident Commission; affiliated with Multnomah and Emanuel hospitals; in 1935 was named by President Roosevelt as a member of the advisory committee of orthopedic surgeons to Georgia Warm Springs Foundation; on Jan. 6, 1938, was designated Portland's "First Citizen of 1937" by the Portland Realty Board; died Oct. 31, aged 67, of coronary thrombosis.

Stinson, William David ⊕ Memphis, Tenn.; born in Salem, Ill., April 15, 1894; University of Michigan Medical School, Ann Arbor, 1920; associate professor of otology, laryngology, and rhinology at University of Tennessee College of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; in 1951 president of the Memphis and Shelby County Medical Society; for many years secretary of the Tennessee Academy of Ophthalmology and Otolaryngology; served as chief and president of the staff of Baptist Memorial Hospital; died in Nashville Oct. 18, aged 59, of arteriosclerotic heart disease.

Fouche, James Sample ⊕ Columbia, S. C.; born in Ninety-Six, S. C., March 20, 1886; Medical College of the State of South Carolina, Charleston, 1912; also a graduate in pharmacy; past president of the Columbia Medical Society and the Alumni Association of the Medical College of South Carolina; served during World War I; from 1920 to 1932 special chest examiner for the U. S. Veterans Bureau regional office in Columbia and from 1928 to 1932 was the chief medical officer; for many years chief of the outpatient service, Veterans Administration; on the staffs of the Columbia, Baptist, and Providence hospitals; died Oct. 11, aged 67, of aneurysm of the abdominal aorta.

Lobsenz, Herbert ⊕ Hopewell Junction, N. Y.; born in Paterson, N. J., Jan. 23, 1920; New York University College of Medicine, New York, 1943; specialist certified by the American Board of Radiology; certified by the National Board of Medical Examiners; served during World War II and was awarded the Bronze Star, the Unit Presidential Citation, the Combat Medical Badge, and other decorations; affiliated with the Veterans Administration Hospital in Castle Point; associate radiologist at St. Francis Hospital in Poughkeepsie; formerly affiliated with the Maimonides Hospital in Brooklyn; died Oct. 18, aged 33, of Hodgkin's disease.

Atkinson, Howell, North Little Rock, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1918; on the courtesy staff of St. Vincent's Infirmary in Little Rock; died Oct. 19, aged 69, of coronary occlusion.

Barnett, Thomas Meriwether, Atlanta, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; served during World War I; retired chief surgeon of the old U. S. Veterans Hospital No. 48; died Sept. 27, aged 74, of coronary occlusion and arteriosclerosis.

Bartecchi, Ferdinand Aloysius ⊕ Scranton, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1920; director of public health; formerly county coroner; died Oct. 23, aged 56, of coronary thrombosis.

Donovan, William Henry ⊕ Iowa City, Iowa; State University of Iowa College of Medicine, Iowa City, 1907; died in the Mercy Hospital Sept. 1, aged 69, of Staphylococcus aureus bacteremia.

Fecteau, Adelard, St. Petersburg, Fla.; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Canada, 1895; served as city physician and as a member of the city board of health; on the staff of the Fall River General Hospital; died Oct. 14, aged 82, of aplastic anemia and arteriosclerotic heart disease.

Fergusson, Frederick William ⊕ Lodi, Calif.; Northwestern University Medical School, Chicago, 1918; past president and vice-president of the North Dakota State Medical Association; served as a member of the state board of medical examiners of North Dakota; died Sept. 5, aged 61.

Foley, Francis Edward, New Haven, Conn.; Yale University School of Medicine, New Haven, 1914; for many years physician for the State Athletic Commission; formerly on the staff of the Hospital of St. Raphael; died in North Westport, Mass., Oct. 15, aged 68.

Freas, Martin Wesley ⊕ Berwick, Pa.; Jefferson Medical College of Philadelphia, 1914; past president and vice-president of the Columbia County Medical Society; served during World War I; affiliated with Berwick Hospital; died Oct. 11, aged 64, of a cerebral accident.

Freeland, Frank, Maywood, N. J.; University and Bellevue Hospital Medical College, New York, 1901; died in Hackensack (N. J.) Hospital Oct. 22, aged 77, of acute left ventricular failure.

Fruth, Harold Edgar, Columbus, Ohio; Chicago College of Medicine and Surgery, 1915; served in France during World War I; physician for the Pennsylvania Railroad; died in Fostoria Oct. 13, aged 60.

Girouard, Joseph Arthur ⊕ Willimantic, Conn.; Baltimore Medical College, 1899; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; on the staff of the Windham Community Memorial Hospital; died Sept. 29, aged 78, of coronary thrombosis.

Gobar, Franklin Harold ⊕ Fullerton, Calif.; Stanford University School of Medicine, San Francisco, 1924; served during World War I; past president of the Orange County Medical Society; died Oct. 16, aged 63.

Good, Charles Frederick ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1927; specialist certified by the American Board of Pediatrics; served during World War II; medical supervisor of public schools in Cleveland; affiliated with the Babies and Childrens Hospital; died Oct. 16, aged 52, of arteriosclerotic heart disease.

Gordon, Donald Louis, Oscoda, Mich.; McGill University Faculty of Medicine, Montreal, Canada, 1939; served during World War II; died in the Hackensack (N. J.) Hospital Sept. 2, aged 44, of massive intestinal hemorrhage and thrombosis with embolism to lung.

⊕ Indicates Member of the American Medical Association.

Grillo, Vincent James ⊕ New Haven, Conn.; Yale University School of Medicine, New Haven, 1933; *specialist certified by* the American Board of Orthopaedic Surgery; certified by the National Board of Medical Examiners; affiliated with Newington (Conn.) Home and Hospital for Crippled Children, Grace New Haven Community Hospital, and Hospital of St. Raphael; died recently, aged 44.

Hall, Fred Watt, Rome, Ga.; College of Physicians and Surgeons, Memphis, Tenn., 1907; consulting surgeon, Central of Georgia Railroad; died Oct. 2, aged 72, of myocardial infarction and arteriosclerosis.

Hansen, Charles Ola, Long Beach, Calif.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; served during World War I; died Oct. 8, aged 86, of arteriosclerotic heart disease.

Harris, George Gano ⊕ Helena, Okla.; University of Oklahoma School of Medicine, *Oklahoma City, 1917;* served during World War I; twice president of the Alfalfa County Medical Society; affiliated with Masonic Hospital in Cherokee and the Enid (Okla.) General Hospital; died in Enid Sept. 30, aged 66, of coronary occlusion.

Hatchett, William Clifton, Hollywood, Fla.; Memphis (Tenn.) Hospital Medical College, 1912; for many years county health officer; served during World Wars I and II; died Oct. 26, aged 65, of a heart attack.

Hawley, Nelson Joy, Webster Groves, Mo.; Washington University School of Medicine, St. Louis, 1895; served during World War I; died in the Veterans Administration Hospital in Jefferson Barracks Oct. 1, aged 81, of arteriosclerosis.

Henritzy, Oscar Edwin, Port Matilda, Pa.; Medico-Chirurgical College of Philadelphia, 1898; also a graduate pharmacist; died in Altoona (Pa.) Hospital Sept. 30, aged 81.

Hood, Charles Sumner ⊕ Ferndale, Wash.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1902; an Associate Fellow of the American Medical Association; formerly affiliated with the Indian Service; served during World War I; county coroner; on the staff of St. Joseph's Hospital in Bellingham; died in the Virginia Mason Hospital in Seattle Sept. 15, aged 79, of cerebral hemorrhage.

Houck, William Seibert, Harrisburg, Pa.; Medico-Chirurgical College of Philadelphia, 1914; also a minister; affiliated with Keystone Hospital; died Oct. 5, aged 67, of a heart attack.

Ivec, Martin J. ⊕ Joliet, Ill.; Rush Medical College, Chicago, 1904; died in September, aged 74.

Jackson, Bruce Emmett ⊕ Chicago; Chicago Medical School, 1927; served during World War II; died Oct. 21, aged 52, of coronary occlusion.

Jennings, Edward S. ⊕ Spokane, Wash.; Milwaukee Medical College, 1909; an Associate Fellow of the American Medical Association; member of the North Pacific Surgical Association; died in the Sacred Heart Hospital Oct. 8, aged 72.

Jermstad, Robert James ⊕ Flint, Mich.; Rush Medical College, Chicago, 1934; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; served during World War II; affiliated with McLaren, Hurley, and St. Joseph hospitals; died in the Leila Y. Post Montgomery Hospital in Battle Creek Oct. 15, aged 45, of injuries received in an automobile accident.

Jerrick, Walter Fitzgerald ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1919; died in the Hospital of the University of Pennsylvania Oct. 23, aged 59, of hypertensive arteriosclerotic heart disease with renal failure.

Jobes, John Bell, Washington, Pa.; Eclectic Medical Institute, Cincinnati, 1896; died in St. Francis Hospital, Pittsburgh, Aug. 30, aged 84.

Jones, Frank Collett, Frankfort, Ind.; Chicago Medical College, 1889; died in the Clinton County Hospital Oct. 17, aged 90, of carcinoma of the sigmoid.

Jones, Maurice Leland ⊕ Kansas City, Mo.; Rush Medical College, *Chicago, 1930; specialist* certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; at one time on the faculty of the University of Tennessee College of Medicine, Memphis; affiliated with Veterans Administration Center in Wadsworth, Kan.; died in St. Luke's Hospital July 20, aged 52, of uremia following surgery.

Jost, William Edward ⊕ St. Louis; St. Louis College of Physicians and Surgeons, 1906; died in the Alexian Brothers Hospital Sept. 18, aged 73.

Kauffman, Ira Dwight, Long Beach, Calif.; Chicago Homeopathic Medical College, 1901; died Aug. 23, aged 78, of carcinoma of the colon and liver.

Kownacki, Francis Joseph ⊕ Philadelphia; Temple University School of Medicine, Philadelphia, 1919; affiliated with Frankford Hospital, Episcopal Hospital, and St. Mary's Hospital, where he died Oct. 21, aged 58, of coronary occlusion.

Lang, John Henry ⊕ Fullerton, Calif.; St. Louis University School of Medicine, 1906; member of the Industrial Medical Association; died Aug. 1, aged 71, of coronary thrombosis, diabetes mellitus, and of an injury received in a fall.

Lipkis, Abram, Los Angeles; Denver and Gross College of Medicine, 1907; died Aug. 18, aged 78, of acute myocardial infarction, hypertension, and arteriosclerotic heart disease.

Little, Theodore Alvin ⊕ Erie, Pa.; Baltimore Medical College, 1908; served during World War I; for many years physician at the General Electric Company; died Aug. 16, aged 71, of carcinoma of the prostate.

Lucke, Alexander William, Cleveland; University of Wooster Medical Department, Cleveland, 1897; director of the National Screw & Manufacturing Company and the Cleveland Graphite Bronze Division of the Clevite Corporation; died in the Huron Road Hospital Oct. 12, aged 79, of rupture of the heart.

Lurie, Solomon I. ⊕ Newark, N. J.; The General Medical College, Chicago, 1923; an examining physician for Newark draft boards during World War II; on the staff of Beth Israel Hospital; died in Long Beach, L. I., Sept. 7, aged 57.

McLain, William Hay ⊕ Wheeling, W. Va.; Rush Medical College, Chicago, 1896; died in St. Francis Hospital, Pittsburgh, Aug. 14, aged 79, of arteriosclerosis.

Miller, Edward Bernard, Stevens Point, Wis.; Chicago Medical School, 1935; served during World Wars I and II; died in St. Michael's Hospital, Oct. 1, aged 59, of hemiplegia, arteriosclerosis, and hypertension.

Robinson, Jay Aaron ⊕ Trenton, N. J.; Georgetown University School of Medicine, Washington, D. C., 1942; certified by the National Board of Medical Examiners; deputy coroner of Mercer County; served during World War II; affiliated with St. Francis Hospital; died in the George Washington Hospital, Washington, D. C., Oct. 20, aged 37, of acute poliomyelitis.

Russell, James Andrew Merle ⊕ Erie, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1917; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Erie County Medical Society; served on the staffs of the Hamot and St. Vincent's hospitals; died Aug. 18, aged 61, of coronary thrombosis.

Strauss, Fletcher Louis ⊕ Chicago; Rush Medical College, Chicago, 1897; an Associate Fellow of the American Medical Association; died in the Sherman Hospital, Elgin, Ill., Oct. 20, aged 77, of carcinoma of the stomach.

Sullivan, Walter Thomas Jr. ⊕ Bronxville, N. Y.; Cornell University Medical College, New York, 1940; interned at Albany (N. Y.) Hospital; affiliated with the Lawrence Hospital, where he died Oct. 29, aged 43, of coronary occlusion.

Trombley, Bryan ⊕ Detroit; Detroit College of Medicine and Surgery, 1921; on the staff of the Evangelical Deaconess Hospital; died in Santa Barbara, Calif., Sept. 15, aged 57, of coronary thrombosis.

FOREIGN LETTERS

BRAZIL

Duodenum-Lung Circulation Time in Portal Hypertension.—At a meeting of the Associação Paulista de Medicina, Drs. N. Moraes Barros, Octavio M. Dantas, and Palmiro Rocha presented a paper describing a study of the duodenum-lung circulation time in 38 patients (12 normal persons, 5 with diseases that do not interfere with the portal system, and 21 with a disease affecting the portal system). Although they found a striking difference between the circulation time in normal persons and in those with portal hypertension, there was an overlapping of the two groups between the values 30 and 40 seconds, suggesting an absence of hypertension when the time is less than 30 seconds and the presence of hypertension when the value is greater than 40 seconds. There was no significant difference between the duodenum-lung circulation time before and after an operation for a condition not involving the portal system, thus permitting the use of this determination as a test of the circulatory condition of the portal system. Quite different results were obtained in the patients on whom operations were performed that involved the portal system; of these 13 had splenorenal anastomosis, 3 had splenectomy, and 5 had ligation of the hepatic and splenic arteries. In all these patients, the duodenum-lung circulation time was lower after than before the operation. The duodenum-lung circulation time is not convenient for the study of the permeability of the venous shunt, nonsignificant differences having been found in patients on whom other types of operations were performed.

Postpartum Necrosis of the Anterior Hypophysis.—At a meeting of the Associação Paulista de Medicina, Drs. Cassio Bottura, Moacyr T. Verissimo, and Renato H. Migliorini presented a report on four cases of panhypopituitarism resulting from postpartum ischemic necrosis of the anterior hypophysis. A history of hemorrhage during the previous delivery and the subsequent clinical findings did not leave any doubt about the diagnosis. Owing to the psychic condition of such patients, the obstetric history is often inconclusive. The clinical findings are a combination of the signs and symptoms of gonadal, thyroid, and suprarenal insufficiencies. In making their diagnoses, the authors used the basal metabolic rate and the serum cholesterol level to assay the thyroid function; the Robinson-Power-Kepler test, the response of the eosinophils to corticotropin (ACTH) and epinephrine (Suprarenin), the tolerance to glucose and insulin, the blood sodium, potassium, and chloride levels, and the determination of the urinary 17-ketosteroids and corticoids to determine the suprarenal insufficiency; the colpocytology to ascertain the gonadal insufficiency in women; and the low urinary elimination of the gonadotropins to disclose the hypofunction secondary to a hypophyseal lesion. The absence of visual defects or roentgenographic alterations in the sella turcica ruled out the possibility of a tumor causing the hypophyseal lesion. These procedures, permitting the determination of the glandular insufficiency, even in the absence of pathognomonic clinical findings, enable the practitioner to make a surer diagnosis of the disease and prevent confusion with similar clinical entities, particularly with anorexia nervosa. The four patients described by the authors were in relatively good general condition with about normal body weight. This fact supports the belief that cachexia is not an essential symptom of panhypopituitarism.

Intermediate Nephron Nephrosis in Crotalic Poisoning.—The problem of the lesions caused by rattlesnake venom in man has been incompletely studied up to now. Drs. M. Freitas Amorim and R. Franco de Mello of the São Paulo Butantan Institute studied three fatal cases and found chiefly degenerative and necrotic phenomena, especially on the ascending part of the Henle loops and the distal convoluted tubules, with casts that gave positive hemoglobin reaction. The casts were also numerous in the medullar zone, in the interior of the ducts of Bellini. In two of the patients, there was, in the intermediate zone of the kidney and the cortex around the more degenerated tubules, an inflammatory and interstitial neutrophilic granulocytic reaction, with edema and some marked focal hyperplasia of histiocytes. In the medullary zone, however, the ducts of Bellini contained only casts, without any degeneration or necrosis and, consequently, without any inflammatory reaction in that region. This gives the medullary zone the appearance of a "clearing," in contrast to the intermediate and cortical zones of the parenchyma that present a less clear pattern because reactionary inflammatory lesions are present.

Such lesions may closely resemble those first described by Hackradt and by Minami under the name of burial nephrosis, by Bywaters and Dible as a crush syndrome, and later by Lucke as lower nephron nephrosis. These are characterized, in general, by myohemoglubinuria or simple hemoglobinuria or by hemolytic anemia, such as found in metallic poisonings, toxemia of pregnancy, falciparum malaria, and transfusion of incompatible blood. Lesions of this type, however, have never been described in patients with snake bite. The authors object to the designation of this condition as lower nephron nephrosis. They prefer to regard it as an intermediate nephron nephrosis. They stress the necessity of reserving the term lower nephron nephrosis for those patients in whom degenerative and necrotic lesions in the medullary zone of the kidney predominate, as in the renal lesions associated with gout.

Ovarian Cysts with Twisted Pedicles.—Ovarian cysts with long pedicles, even those of large volume, produce clinical symptoms only when there are complications in their evolution. Among these complications the most frequent is torsion of the pedicle. The clinical findings, in general obscure, may then be changed by the rapid appearance of continuous or intermittent pain of varying intensity. To study the main features of the ovarian cysts with twisted pedicles, Dr. B. Neme analyzed the last 28 records of that condition seen in the obstetrical department of the Hospital das Clinicas (São Paulo State University) and published a report on this study in *Revista de Gynecologia e d'Obstetricia* (47:503, 1953). He found that this condition is rather rare, as demonstrated by the existence of only 28 cases in the files of the hospital between 1945 and 1952. The patients were from 19 to 53 years old; 5 were pregnant (2 with ectopic pregnancy); 22 were multiparas; and in 18 the involvement was on the right side. The torsions did not exceed five turns and the local lesions consisted only of hemorrhage of the wall or into the cavity of the cyst. Of the 16 cysts for which the type was recorded, 10 were serous cystadenomas, 3 were dermoid cysts and cysts of the corpus luteum, 2 were pseudomucinous cystadenomas, and one was a papilliferous cyst. The symptoms included pain in the lower abdomen in all patients (95% homolateral), tumor mass in 92.8%, nausea and vomiting in 75%, temperature elevation in 45.7%, and rebound tenderness in 42.8%. Puncture of the pouch of Douglas and radiography are helpful diagnostic procedures.

Revision of the Chromogenic Strains of the Genus Neisseria.—Dr. J. de Toledo Mello, São Paulo State University, studied the genus Neisseria and the systematic position of the flava subgroup of aerobic strains that develop well on ordinary culture mediums. No justification for the maintenance of the perflava and subflava species was found. Fermentation reactions in this group of bacteria are unstable and uncertain and may thereby give rise to an increase in the number of strains reported according to the amount of carbohydrates used. The Neisseria flavescens (Branham 1930), inactive on the four carbohydrates used for the identification of chromogenic strains of the Neisseria group, presents the same culture

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

reactions described by Gordon in 1921. Its characteristics as a new species were based on serologic data obtained in agglutination tests, considered without value for the study of this group. It is suggested by Mello that the yellow strains of the Neisseria genus that do not grow on ordinary culture mediums be classified as a single species and be referred to as Neisseria flava (Bergey and others).

FINLAND

Duration of BCG Allergy.—The duration of BCG (bacille Calmette Guérin) allergy, as determined by the persistence of a positive tuberculin reaction after BCG vaccination, may be judged incorrectly when exposure to infection with virulent tubercle bacilli has by itself assured a positive tuberculin reaction. To avoid this element of confusion, the ideal would be to keep persons who are vaccinated with BCG under close supervision and out of contact with open cases of tuberculosis. With this ideal in mind, Dr. Ole Wasz-Höckert and Dr. Märta Donner of Helsinki have followed the tuberculin reactions of the inmates and staffs of six institutions for mental defectives. Since 1949, 565 members of these staffs have been tested, and 269 of them showed negative reaction to an injection of 1 mg. of tuberculin. As many as 224 of these 269 negative reactors were vaccinated with BCG. The vaccination was effected by intracutaneous injection, and the tuberculin testing that was carried out three months later was repeated twice a year with from 0.01 mg. to 1 mg. of tuberculin. The vaccinated subjects were also kept under yearly radiological control. The absence of infectious cases of tuberculosis in the environment of these persons was indicated by the persistence of negative tuberculin reactions several months before they were vaccinated with BCG. This investigation, recorded in *Nordisk Medicin,* Aug. 20, 1953, showed that among 200 vaccinated persons four (2%) were tuberculin-negative half a year after vaccination. This percentage was raised to 7.5% after one year, to 10.4% after one and one-half years, and to 29.5% after two and one-half years. It would thus seem that the tuberculin allergy effected by BCG does not last long in a large proportion of cases.

Cesarean Section.—At the University Gynecological Hospital in Helsinki, lately there has been a definite tendency to liberalize the indications for cesarean section. In his address at a meeting in 1952, Prof. Paavo Vara pointed out that at this hospital cesarean sections had constituted only 1.5% of the confinements in 1925, whereas the corresponding figure for 1950 was 5.38%. A recent study by Dr. Erik Aschan and Dr. Olavi Kinnunen from the same hospital reflects the same trend. Among 46,877 confinements at this hospital in the period 1945-1951, 151 were complicated by transverse and oblique positions of the infant. In 94 cases delivery was by cesarean section with the loss of only one infant. In 25 cases internal version was undertaken with the loss of four infants, and in 32 cases external version was undertaken with the loss of one infant. These figures give some support to the disapproval of internal version for transverse and oblique positions. The authors concluded that if external version fails and the patient is a primipara, Cesarean section is the method of choice. The same rule applies to multiparas with a narrow pelvis, placenta previa, early rupture of the membrane, or prolapse of the umbilical cord or a limb. In other patients delivery can be effected by the normal route.

The Early Diagnosis of Cancer of the Stomach.—Two recent articles in the Scandinavian medical press, both by Dr. Harry E. Bloomquist of the Maria Hospital in Helsinki, dealt with 372 patients with cancer of the stomach treated at this hospital in the 20 year period 1926-1945. About 25% of these patients presented signs and symptoms of cancer of the stomach two months or less before medical examination. In about 44% this interval was four months or less, and in about 60% this interval was six months or less. In only about 20% had this interval lasted longer than a year. A comparison of the length of this interval with the operability of the disease suggested that the shorter the interval the worse the prognosis; thus, in as many as 67 of 77 patients with a history of symptoms for two months or less the disease was found to be inoperable. In other words, it is the degree of malignancy that determines the prognosis irrespective of the previous duration of symptoms.

Although Blomquist has found a radiological examination capable of indicating a malignant tumor in 78.5% of his patients, he doubts the value of mass radiography of the stomach on the lines followed for wholesale examinations for pulmonary tuberculosis, because a radiologist could not make more than 20 such examinations daily and if a prophylactic radiological examination were to be made four times a year of the million inhabitants of Finland over the age of 40 years, 7,500 radiologists would be required for this service alone. The three month interval between examinations was based on the fact that about 50% of his patients had presented symptoms for less than four months. Even if prophylactic radiological examinations were to be confined to patients with chronic gastritis, the task would be far too great considering the high frequency of this condition. Blomquist found a palpable tumor in about 50%, free hydrochloric acid in 20.5%, blood in the feces in 75%, hemoglobin concentration (Sahli) of 80% or more in only 27.8%, and a normal sedimentation rate in 75% of the patients in this series.

Chemotherapy of Primary Exudative Pleurisy.—At a hospital in Åbo, comparative studies of various methods of treating primary exudative pleurisy have been undertaken. These studies, reported by Dr. Lennart Kalliomäki in *Duodecim,* incorporated in *Nordisk Medicin* for June 17, 1953, deal with three groups of patients. The first group, treated in 1947, contained 54 patients for whom rest in bed, tonics, and salicylic acid (Salicyl) were prescribed. The second group consisted of 40 patients who were treated with *p*-aminosalicylic acid (PAS). The third group consisted of 36 patients who, in addition to *p*-aminosalicylic acid given by the mouth, were given intramuscular injections of streptomycin. All the patients were kept in the hospital till they had become completely afebrile, and the sedimentation rate had fallen. Aspiration of pleural fluid was undertaken only when it was indicated by dyspnea. The comparative merits of the treatment the patients received in each of these three groups were examined in the light of the duration of the fever and the behavior of the sedimentation rate. The behavior of the sedimentation rate was much the same in all three groups, and there was no statistically significant difference in the duration of the fever.

LONDON

The General Practitioner and Lay Education in Cancer.—Lord Horder, chairman of the British Empire Cancer Campaign, stated in *Lancet* that those who favor a campaign of intensive lay education argue that even at the worst it must bring to light some patients in the earlier and potentially curable stage and that in any case a policy of diffusing knowledge is more likely to abolish than to create fear, which is largely born of ignorance. Those who take the opposite view argue that the best course is the strengthening of the relationship between patient and family doctor and that a policy that risked the danger of producing cancer neurosis might render the physician's task more difficult by keeping some genuine but fearful cancer patients away and by overloading the physician with cases of carcinophobia. Accordingly the cancer campaign issued a questionnaire asking all general practitioners: "Do you consider that the launching of a scheme of lay educational propaganda on cancer (by pamphlet, lectures, films, etc.) would be of assistance in securing the earlier diagnosis of cancer, and thereby improving the chances of a cure?" To 21,040 letters there were 5,053 replies, which is considered a high proportion of replies to this type of questionnaire. Of the replies, 2,148 were an unqualified "yes" and 2,683 an unqualified "no." The accompanying letters showed that a large number of practitioners had given much thought to the matter. Lord Horder makes no comment on these figures, but says that on the strength of them, the campaign will consider the matter further.

Clinical Research in the National Health Service.—Under the National Health Service Act of 1946, the Minister of Health was empowered to undertake research or to help others to do so, and a Clinical Research Board will be set up, to be responsible for promoting clinical research on a national basis. If the research organization is to work, there must be effective machinery for consultation at all levels, and provision is made for this. Careers in clinical research will be equated in all material respects with careers in the National Health Service. Research units will not be imposed on hospitals, nor will clinical research workers be promoted to senior posts without the agreement of the hospitals concerned. It is hoped that regional and hospital authorities will seek the advice and help of the Clinical Research Board about their research projects.

New Maternity Benefits.—Under the National Insurance scheme the maternity grant will be increased from $11.20 to $25.20 effective Oct. 26, 1953, and there will be an additional new grant of $8.40 for home confinements. For women not employed outside their own home duties, the home confinement grant of $8.40 will take the place of the former attendance allowance of $2.80 a week for the four weeks immediately after the date of the confinement. Women ordinarily working for an employer or self-employed will receive the $8.40 home confinement grant and a maternity allowance of $4.55 for the 18 weeks starting 11 weeks before the expected date of confinement, with additions in certain circumstances for dependents. This is instead of the present maternity allowance of $5.05 for the 13 weeks starting six weeks before the expected date of confinement. The home confinement grant will also be awarded for confinements that take place in any other institution or accommodation, such as a private nursing home, so long as the cost of accommodation and maintenance does not fall on public funds.

Hospital Priority for War Pensioners.—After transfer of the function of the Ministry of Pensions, priority will be given at all National Health Service hospitals to war pensioners needing examination or treatment for any condition related to the disability for which they are pensioned. This priority will be given subject only to the needs of emergency and other urgent cases that must take precedence, and hospital authorities are being asked to ensure that it is afforded in all cases where a condition related to an accepted disability is involved. Civilian and mercantile marine pensions will be dealt with in the same way as service pensioners. General practitioners are asked by the Ministry of Health to state clearly when referring war pensioners to hospitals in the National Health Service if the reference is in connection with an accepted disability, so that the necessary priority may be given.

Enrollment in Medicine.—The number of names in the current British Medical Register is 83,914, an increase of 1,658 over the corresponding figure on Jan. 1, 1952. In 1933 the total number on the register was 56,741. The number added by registration in 1952 (4,493) was the highest on record. As against this there were in 1952 an unusually large number of removals under the section of the Medical Act of 1858 that prescribes that names shall be removed after a stipulated period in the absence of any answer to the inquiry, whether there has been cessation of practice or change of address. The number removed under the penal sections of the act is no greater than it was 20 years ago, though in the meantime the total on the register has increased by 40%. The number of students beginning the medical curriculum proper during the year 1952-1953 is estimated at 2,512, which is about 50 fewer than for the previous year.

Under the Medical Act of 1950, full registration is not granted without proof of experience, namely, a certificate that the applicant has been engaged in employment in a resident medical capacity in one or more approved hospitals or institutions (including an approved health center) for the period prescribed by the regulations of the General Medical Council. Jan. 1, 1953, was appointed as the day after which a newly qualified person would not be eligible for full registration until he had, after passing his qualifying examination, served as house officer in one or more such approved hospitals or institutions for 12 months.

British Pharmacopoeia, 1953.—The eighth British Pharmacc poeia, published in March, 1953, became official in Septembe in accordance with the program for quinquennial revisio approved by the General Medical Council. According to th *British Medical Journal* of Sept. 19, 1953, the new numbe contains 115 monographs on substances that were not offici in 1948, and 130 monographs of the previous edition hav been deleted. The immediate impressions on opening th volume are the novelty of the English titles, the new arrang ment of the monographs, and the clarity of the printed matte No longer do we find "Toxinum Diphthericum Detoxicatum but "Diphtheria Prophylactic," not "Oculenta—Ointments f the Eye" but "Eye Ointments." The names of many oth preparations have been rationalized, so that, for example, th words "aspirin tablets" and not only "tablets of aspirin" no connote an official article. By the new arrangement of th monographs, preparations such as ointments, injections, tablets follow immediately after the monograph on the acti ingredient, and, although this will be a convenience to phys cians and analysts, it will demand changes in the habits thought of pharmacists. Some comment on the change fro Latin to English titles was made at the recent British Pharm ceutical Conference, at which there was a debate between tho for and those against the writing of prescriptions in Englis instead of Latin. Prof. A. D. Macdonald said that medic and chemical specialists, in their comments on the ne pharmacopoeia, seemed to support English to a man. Th pharmacists were about 2 to 1 in favor.

The introduction to the new pharmacopoeia contains i formative tables showing the rejections and selections ma by the Pharmacopoeia Commission. Nineteen vegetable dru and their numerous tinctures, infusions, syrups, and extrac have been deleted either because of their therapeutic i adequacies or because the active principle, for exampl ergonovine, is available as a pure stable substance. All th pharmacopoeial pills and lozenges (except penicillin lozenge the liniments of aconite and of belladonna, and some spiri and little-used injections no longer appear. Capsules ar implants have been introduced as a dosage form of certa medicaments. In the list of additions the modern synthet chemicals and the antibiotics appear most frequently. Penici lin and procaine penicillin, the streptomycins, chlortetracycli (aureomycin), and chloramphenicol, with their preparation account for 15 monographs not present in the 1948 editio Among other monographs appearing for the first time a those on methadone, phenadoxone hydrochloride, globin zi insulin, scarlet fever antitoxin and prophylactic, cyanocobal min (vitamin B_{12}), and sodium aminosalicylate.

The statements on dosage of the drugs show two gener changes; both might be taken with advantage a step furth in the next edition. Doses are given only in the metric syste except for substances and preparations commonly used prescribed in the Imperial system. Grain doses for the sulfon mides and sex hormones and minim doses for typhus vaccin are omitted. The tendency to expand information on dosag increases the value of the book to the prescriber. For methy thiouracil and propylthiouracil the controlling dose and th maintenance dose are now given; for sodium iodide there a dose for the treatment of thyrotoxicosis; and the dose picrotoxin is given for treatment of barbiturate poisoning.

White Bread.—Statutory orders that came into force on Au 30 have removed the restrictions on the extraction rate o flour, thus permitting a return to the white loaf. The orde require, however, that calcium in the form of creta praeparat (1 oz. to 20 lb. or 1 gm. to 320 gm.) shall be added to al flour; and that iron, thiamine, and nicotinic acid shall b added to flours of extraction rate lower than 80%, the rat for national flour. Only bread made from national flour re mains controlled in price.

Artificial Sweeteners in Food.—In the future only sacchari will be permitted as an artificial food sweetener (Artificia Sweeteners in Food Order, 1953). This follows a recom mendation from the Medical Research Council. Saccharin i known to be harmless, but according to the Council's Foo Adulterants Committee the use of certain other artificia sweetening agents may be dangerous to health.

CORRESPONDENCE

DEATH AND DISTINCTION

To the Editor:—It is well known that, during the first half of the present century, there was a marked increase in the expectation of life for both sexes. The purpose of this letter is to suggest that those members of the medical profession, who belong to that branch of the profession that has played the greatest part in this achievement, have not themselves shared in the achievement and why this is so. Advantage has been taken of the obituary notices in THE JOURNAL in which the cause of death is stated in a high proportion.

From the beginning of 1950, two series of extracts have been prepared, one containing those persons selected for distinction in as far as they were placed first in the lists without regard to alphabetical order and one containing those whose notice failed to occupy the whole of three lines. That such a method of distinguishing prominent members of the medical profession may involve injustice cannot be denied; in general, however, it must distinguish between success and failure in relation to the particular standards involved.

To obtain 500 consecutive notices in each group in which both the age of the subject and the cause of death was stated, 1,313 entries were abstracted; in 313 the age but not the cause of death was noted. The average age of death for these two groups was then calculated: distinguished, 578 persons with average age 67.1 years, and undistinguished, 735 persons with average age 72.3 years. The difference of 5.2 years in the expectation of life between the two groups is obviously significant, and the following table shows the distribution of deaths within them according to age.

	Distinguished		Undistinguished	
Age, Yr.	Number	% of Total	Number	% of Total
Under 40	7	1	15	2
40-49	45	8	23	3
50-59	90	16	55	8
60-69	170	29	164	22
70-79	180	31	254	35
80-89	73	13	185	25
90 and over	13	2	39	5
Total	578	100	735	100

Taking the biblical figure of three score years and ten as an adequate expectation of life for those who reach maturity, it will be noted that, while 65% of the undistinguished reached this goal, only 46% of the distinguished did so.

In the analyses of the causes of death of 500 persons in each of the two groups, the outstanding features are the low incidence of fatal disease of the respiratory tract, resulting from the discovery of sulfonamides and antibiotics, and the high incidence of cardiovascular degeneration. The major causes of death are listed in the following table.

	Distinguished		Undistinguished	
Cause of Death	Number	%	Number	%
Cardiovascular	325	65.0	332	66.4
Respiratory	23	4.6	25	5.0
Neoplastic	78	15.6	66	13.2
Accidental	24	4.8	21	4.2
Miscellaneous	50	10.0	56	11.2
Total	500		500	

It is clear that there is no significant difference between the two groups in the percentage of deaths resulting from any of the main causes, and it, therefore, appears that the difference in the average age of death between the distinguished and undistinguished must be due to a different age incidence for death in one or more of the groups. The following table shows an analysis of the figures to demonstrate this, excluding the accidental deaths and those resulting from miscellaneous causes.

	Distinguished		Undistinguished	
	Number	Average Age	Number	Average Age
Cardiovascular disease	325	67.2	332	72.5
Respiratory disease	23	75.5	25	77.8
Neoplasms	78	65.1	66	74.3
Total	426	67.6	423	73.1

It is of interest that, although the figures in this series are not large, the age incidence of neoplasms in the two groups shows as marked a disparity as that for cardiovascular diseases, a finding that certainly warrants further investigation.

The figures for deaths resulting from cardiovascular disease are sufficiently large to indicate that the distinguished have a poorer expectation of life than the undistinguished in this respect, and a further analysis (the next table) shows this to be due not only to the incidence and age occurrence of coronary occlusion, but to a trend involving all types of cardiovascular deterioration.

	Distinguished			Undistinguished		
	Number	%	Average Age	Number	%	Average Age
Coronary occlusion	164	50.5	65.1	135	40.7	69.0
Cerebrovascular accidents	54	16.6	69.3	76	22.9	75.4
Arteriosclerosis and hypertension	43	13.2	72.3	34	10.7	79.3
Unspecified and miscellaneous heart disease	64	19.7	69.3	87	26.2	72.5
Total	325		67.2	332		72.5

It is to be noted that in all groups the average age of death is substantially lower in the distinguished persons. The higher proportion and lower average age of deaths attributed to coronary occlusion are prominent factors. The following table shows the distribution of these deaths by age groups.

	Distinguished		Undistinguished	
Age, Yr.	Number	%	Number	%
Under 40	1	0.6	2	1.5
40-49	13	7.9	5	3.7
50-59	32	19.5	15	11.1
60-69	61	37.2	40	29.6
70-79	44	26.8	50	37.0
80-89	12	7.3	22	16.3
90 and over	1	0.6	1	0.7
Total	164		135	

These figures show that, whereas 65% of the coronary deaths in the distinguished occurred before the age of 70, only 46% did so in the undistinguished. In order to confirm the low average age of death from coronary occlusion in the distinguished, all deaths attributed to this cause in this group were abstracted for the years 1947 to 1949 inclusive. This gave 175 more deaths with an average age of 64.2 years, of which 65% (the same figure as in the first group) were under 70 years. These combined figures, therefore, appear to warrant the conclusion that coronary occlusion is a more important cause of premature death in distinguished as opposed to undistinguished members of the medical profession.

The Registrar-General's "Occupational Supplement" (England & Wales) covering 1930-1932 indicates that the medical profession is prone to coronary disease, even at that time, over 3½ times that of the rate for average men and more than 10 times that of agricultural laborers. The question as to whether a successful, as compared to an unsuccessful, professional career contributes to this risk is a fresh problem, and the evidence presented indicates that it deserves careful consideration.

In the Harveian Oration for 1946, as reported in *The Lancet*, Sir Maurice Cassidy posed the question "Does the population really work harder or live more strenuous lives than their grandfathers did?" He gave as his reply that he doubted it. Both the question and the answer appear to miss the point. The weight of the increased incidence of coronary occlusion has fallen on the professional class, and on the medical profession in particular. If the question were put "Does the physician and surgeon of today live more strenuously and more anxiously than those of two generations past?" the only answer possible is "Certainly!" It is unfortunate that the Victorian was reticent about his age and that the obituary notices of that period seldom stated the cause of death, so that an adequate comparison of a physician's life expectancy then with that today is difficult to make. Between 1897 and 1916 there died 258 members of the medical profession in England who were sufficiently distinguished to be included in "Who's Who" and whose date of birth was mentioned in that work. The following table shows the percentage dying from all causes in the various age groups, and it indicates that the life expectancy for the distinguished has not improved.

Age, Yr.	Who's Who (1897-1916)	The Journal (1950-1952)
Under 40	2%	1%
40-49	4%	8%
50-59	14%	16%
60-69	29%	29%
70-79	29%	31%
80-89	18%	13%
90 and over	3%	2%
Average age	69.5 yr.	67.1 yr.

It seems contrary to obvious facts not to conclude that the medical profession has maintained its financial and social status by working twice as fast with the aid of mechanical devices. Though to the conservative physician the attribution of such organic disease, as is involved in the atheroma-arteriosclerosis-hypertension syndrome and its lethal complications, to anything so nebulous as the psychosomatic concept of mental exhaustion and anxiety is obnoxious, it cannot be denied that evidence in favor of this view is accumulating steadily. As has been remarked by R. H. Ward, "We do not live in an age of reason or even in an age of romance, but in the age of anxiety," and it is upon those who live by their intellect, if not by their intelligence, that the impact of such an age must fall.

WEAKNESSES OF SCIENTIFIC LITERATURE

To the Editor:—This is an appeal to you, and to other scientific editors, for a realistic appraisal of the difficulties that minimize greatly the value of scientific literature to physicians. After discussing this situation over a period of 10 years with physicians who have been out of medical school for 5 years or longer, I feel my criticisms are valid and worth while.

First of all, all or most lecturers, authors, editors, and publishers presuppose an intimate and fresh knowledge of histology. The obvious fact is that this is not so. The great majority of physicians who open a book on pathology and look at a microscopic illustration are frustrated because they have little or no concept of what is being seen, shown, or meant. Why can't these microscopic illustrations have legends, or arrows, as in the book by Netter and others? This way the physician eventually knows what he is seeing. Certainly the need for help is greater in illustrations of pathological conditions than in anatomic illustrations. Without recent instruction in histology, which the majority of physicians forget soon after being out in practice, all pathology illustrations are buried in an envelope of vincible ignorance that precludes easy understanding unless simple help is given by means of arrows or legends.

While the use of designations such as kilograms, grams, decimals for fractions of doses, centimeters, and centigrade temperatures is scientific, they greatly minimize the value of articles written primarily for American readers; few will take time to translate these terms into the understandable and familiar pound, gram, ounce, grain, inch, and Fahrenheit equivalents. If written in familiar terms, an American reader would have a quicker grasp, insight, and picture, while the foreign reader would have a greater motivating reason to translate them in his terms.

Why are the terms "the former and latter" used so often when it would be much easier to repeat, and to remember, "the former and latter" statement, especially a paragraph later? It is a source of irritation and it is a psychological obstruction. As a result, the purpose or value is minimized.

Because of the avalanche of literature a general practitioner has to, or should, read and because of a lack of time and/or mental inertia, anything that will make reading easier or provide a quicker grasp and faster insight is worth while. My points and arguments may be specious. They can be answered by stating that if articles and illustrations are worth while, time should be taken to read them. Because exercise of the intellect implies discipline and more energy than is available at times, I feel that these criticisms are valid and that they should be considered for more realistic reading, understanding, and value on a practical level. To paraphrase Henry Adams: "Nothing in scientific literature is so astounding, as the amount of ignorance that is left in the form of inert facts."

TREATMENT OF RINGWORM OF THE SCALP

To the Editor:—I would like to suggest a method of treatment of ringworm of the scalp, which has been consistently effective in from one to two weeks. Immediate epilation would be ideal. Manual epilation is inefficient because of the tendency of the diseased hairs to break off in the follicles and to leave the bases intact. As a result the hyphae are protected from the fungistatic effect of the medicament. The use of adhesive plaster has been proved equally unsatisfactory for the same reason. Many years ago a barbarous method was employed called the "Tar Cap" or capellus piceus. It consisted of covering the entire scalp with molten tar and then, when it hardened, removing it together with all the hair, normal as well as diseased.

About seven years ago, I tried to find a method by which the diseased hairs could be removed at the beginning of treatment rather than after months of futile effort. I decided on using collodion and it proved eminently successful. At present, I proceed as follows. The normal hair is clipped to about ¼ in. (0.64 cm.) in length in an area about ¾ in. (1.91 cm.) wide around the area involved. The ringworm and the surrounding area are painted with Carbo-fung solution (a proprietary preparation containing alcohol, acetone, resorcinol, phenol, fuchsin, and inert ingredients). When used in this way, this preparation apparently kills the ectothrix spores and, because of its vivid color, gives assurance to school authorities that the child is under treatment. Then several layers of collodion are poured over the ringworm and allowed to dry. The collodion immeshes the stubble of hair down to the scalp. After three days, with ordinary activity on the child's part, the hairs are loosened. The collodion dressing is removed with forceps. There is amazingly little pain. The hairs come out very readily. Normal hair imbedded in the collodion is clipped beneath it. The infected area is free of hair. Thereafter, the mother is instructed to paint the area daily with Carbo-fung solution and to return in one week. In every instance, when the child returned, there was no evidence of fluorescence and no further spread or recurrence. This method combines epilation with the protection of others from contamination.

Footnotes

46. Graduate. Lectures, seminars, and practical experience in administration.

47. Preparation for examination of specialty board in surgery.

48. Preparation for examination of specialty boards *in surgery and surgical specialties.*

49. Arranged according to registration, content and duration.

50. $25.00 Laboratory. $35.00 in part of $100.00 complete course.

51. Interns, Residents, none; Cleveland area M.D.'s, $30.00; other M.D.'s, $60.00.

52. $50.00, residents and $75.00, non-residents.

53. Designed for Nondermatologists.

54. Clinical and basic science course.

55. $75.00 first month, $50.00 each additional month.

56. Graduate. Lectures, seminars and 1 year of practical experience in a hospital.

57. For members of the American Academy of Compensation *Medicine, no fee.*

58. In association with American Academy of Compensation Medicine. Nos. 483 and 484 in consecutive weeks supplement each other and give comprehensive course in industrial medicine.

59. $50.00 for 5 days, $90.00 for 10 days.

60. Registration accepted for 10 days or for the first or second 5-day period.

61. Preparation for board certification.

62. $60.00 total—$10.00 by physician, $50.00 by New York State Department of Health. Limited number of fellowships available.

63. $100.00 total—$10.00 by physician, $90.00 by New York State Department of Health. Limited number of fellowships available.

64. Scientific program for general practitioners.

65. For non-members of the AAGP.

66. Postgraduate scientific meeting.

67. Attendance is encouraged from the following individuals:
   a. Medical Corps Officers of the Armed Forces on active duty.
   b. Medical Corps Officers of the Armed Forces not on active duty.
   c. Physicians from other Federal Agencies.
   d. Other civilian physicians desiring to attend.

68. **Application procedure.** Applications must reach the addressees listed below not later than six weeks before the start of the course.
   a. Forward Applications: From Army Medical Corps officers and full-time Civil Service physicians at Army installations to Office of the Surgeon General, Department of the Army, Washington 25, D. C., ATTENTION: Personnel Division, Career Management Branch.
   b. From Army Reserve Medical Corps officers not on active duty through channels to the Army Area Commander.
   c. From National Guard Medical officers through channels to the National Guard Bureau, Washington 25, D. C.
   d. Of medical officers from other branches of the Armed Forces through regular channels.
   e. Of all others to Commander of the installation conducting the course.

69. Designed for individuals who are board qualified and/or board certified, Chiefs, Assistant Chiefs or Assistant Chiefs of Services, and officers advanced in this specialty.

70. Designed for individuals partially qualified in the specialty or officers responsible for medical treatment in this specialty.

71. From the educational and research viewpoint this symposium for use in national defense should be conducted. Properly handled, it will lead to better understanding of physical and mental health standards and will summarize all information in this field and show areas requiring further study.

72. Open to physicians formally approved and accepted for training in psychoanalysis by Admissions Committee of the Los Angeles Institute for Psychoanalysis.

73. *Plus $5.00 registration fee. Part of M.A.* and Doctoral Training in psychology and psychiatry department. 2 credits.

74. Accredited by the American Psychoanalytic Association for training in the practice of psychoanalysis

75. Open only to psychiatrists who meet the admission requirements of each institute.

76. Open to qualified physicians interested in the application of psychoanalytic theory to the general practice of medicine.

77. 3-yr. course for qualified psychiatrists.

78. Open to qualified physicians by arrangement with the Dean.

79. Open to qualified physicians not specializing in psychiatry.

80. Open to general practitioners of medicine and given in Pittsburgh, Pennsylvania.

81. Advanced candidates in training only.

82. For uncertified specialists and general practitioners; 11 hours' credit in General Practice Academy.

83. Part of resident staff training.

84. Review for general practitioners.

85. Basic science course in preparation for residency in ophthalmology.

86. Basic sciences in ophthalmology.

87. Plus $10.00 laboratory fee.

88. Review for board examination.

89. $40.00 AAGP members; $50.00 non-members.

90. Deals with pedagogical problems.

91. $125.00, personal dissection. $95.00, observation dissection.

92. Practice in diagnosis. Treatment and postoperative care.

93. Florida Clinical Diabetes Association.

94. Florida Medical Association and University of Florida Graduate School.

95. Lillia Babbitt Hyde Foundation.

96. Basic Science course for specialty board certification.

97. Residents $10.00; Physicians and Specialists $25.00.

98. Armed Forces Special Weapons Project, Washington, D. C.

99. Kansas Medical Society.

100. 6 weeks, $25.00; 9 weeks, $37.00; 12 weeks, $50.00.

101. Essex County Medical Society.

102. Baylor University College of Medicine and Houston Heart Association.

103. May also be taken for 3 months at $250.00; 6 months, $500.00; 9 months, $750.00.

104. Radiological Society of Greater Kansas City.

105. $10.00 for non-members; $15.00 members; season $25.00.

106. Enrollment for study leading to degree in industrial health subjects.

Features of Interatrial Defect.—Ten men and nine women between the ages of 17 and 51 years with interatrial defects as diagnosed by cardiac catheterization were studied. The existence of a functioning communication between the atriums was thought probable if the oxygen content of the right atrial blood exceeded that of blood from the innominate vein or superior vena cava by 2 vol. %. The average difference between the two points in the authors' patients was 4.4 ± 1.7 vol. %. The catheter was passed through the interatrial defect in five patients. Functioning interatrial communications may exist for many years without producing symptoms. In 8 of the 19 patients the defect was detected only at the age of 18 or later. Prominent systolic murmurs, usually basal, were frequently observed. Basal systolic thrills that accompanied the murmurs in nine patients may cause diagnostic confusion. Calculations of the pulmonary arterial flow showed that it is often markedly increased but may be only slightly so. Slight to moderate pulmonary arterial hypertension was present in nine of the patients and was moderately severe in two. There is apparently no relation between flow and pressure in the pulmonary arterial system in patients with interatrial defects, but pulmonary vascular resistance is probably low in most of these patients. All but two of the patients showed definite increase in right ventricular pressure work, and in three of them it was more than six times normal. The available data suggested that the kinetic work also was increased significantly, although its absolute value is difficult to determine. The frontal plane QRS vector was usually +90 degrees or more, and right bundle branch block was not uncommon. Some relation between pulmonary flow and frontal plane QRS vector probably exists but could not be established definitely in this study.

Myocarditis in Rheumatic Fever.—Electrocardiographic changes and microscopic observations of the myocardium of 22 patients with rheumatic fever who had died of myocardial failure are reported. Only cases with typical recent Aschoff bodies in the myocardium in the absence of severe valvular deformities were chosen. Most of the patients had been sick three months or less. Shortness of breath, cyanosis, cough, expectoration of bloody sputum, tachycardia, and gallop rhythm were common. Electrocardiographic evidence of myocardial involvement was noted in all cases in which electrocardiographic records were available. In addition to Aschoff bodies, interstitial nonspecific myocarditis was present in every case. In 18 of 22 hearts, the parenchymatous changes noted were characterized by circumscribed foci of necrotic muscle fibers surrounded by small accumulations of endothelial leukocytes, lymphocytes with a few multinucleated cells, and Anitschkow's myocytes. These granulomas resembled Aschoff bodies but varied in some essentials from true Aschoff bodies. It is suggested that the electrocardiographic changes in acute rheumatic fever are due to nonspecific myocarditis.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Cardiorespiratory Function During Altitude Stress.—Marbarger and coworkers report observations on 10 healthy young men, 8 patients with history and symptoms of angina pectoris but without further evidence of acute cardiac disease, and 14 patients with chronic anemia. All subjects were taken to simulated altitudes of 10,000 ft. (10 minutes stay) and 18,000 ft. (10 minutes stay for angina patients and 20 minutes for normal and anemia subjects) in a low pressure, air-conditioned chamber while resting on a horizontal, low frequency, critically damped ballistocardiograph. Measurements were made of arterial blood oxygen and carbon dioxide content and cellular components of blood. Direct tonometry of arterial and venous pressures was performed. Electrocardiographic, ballistocardiographic, and pressure readings and respiratory changes were obtained. 1. Cardiac output increased in all subjects with inhalation of ambient air at reduced barometric pressures existing at 10,000 ft. and 18,000 ft. simulated altitude and promptly returned to ground level values with inhalation of 100% oxygen. 2. Increased cardiac output occurred as a result of an increase in pulse rate and stroke volume in all groups of subjects. 3. Peripheral resistance to blood flow decreased markedly in all groups of subjects on exposure to ambient atmosphere at simulated altitudes up to 18,000 ft. 4. "Useful work of the left ventricle" markedly increased in all subjects during exposure to hypoxia. 5. Mean venous pressure remained unchanged in the normal subjects but increased with duration of stress in both angina and anemia patients. 6. Electrocardiographic changes occurred with hypoxic stress in normal subjects. There was depression or inversion of T-wave and depression of S-T segment. Similar changes were observed in the anemia patients and in those with angina pectoris, although many of the electrocardiograms of the latter group were abnormal before the test was started. 7. The normal group of subjects and the patients with anemia withstood the test throughout the prescribed course, but the angina pectoris group withstood only 10 minutes at 18,000 ft. before anginal pains occurred in some of the patients; the test was discontinued at this time. 8. The over-all responses of the normal and abnormal subjects were so similar that this method cannot serve as a test in persons with questionable evidence of cardiovascular disease. With regard to the advisability of travel by air of patients with cardiovascular disorders, the authors are of the opinion that many patients now advised not to use commercial aviation could travel by air very safely. This is especially true for those persons who have flown prior to presenting evidence of cardiorespiratory disease.

Chlortetracycline (Aureomycin) in Prophylaxis of Rheumatic Fever.—Long-term prophylaxis of rheumatic fever is extremely desirable because the mildness of micrococcic (streptococcic) infections causes them to go unrecognized in many cases and because control of this disease is especially essential to the attack on heart disease as a whole. The use of sulfonamides and penicillin has proved somewhat effective, but unsatisfactory for long-term use, because of toxicity to the patient and development of resistance on the part of the bacteria. A study of 35 patients in Memphis, Tenn., 23 treated with chlortetracycline (aureomycin) and 12 used as a control group, revealed the efficacy of administering 500 mg. of chlortetracycline daily over a period of from 2 to 20 months. Undesirable side-effects were slight, and there was no evidence of the development of resistant strains of group A beta hemolytic micrococci.

Complete Transposition of Great Vessels.—Between 1946 and 1952, 29 cases of complete transposition of the aorta and pulmonary artery were observed by the authors in 17 boys and 12 girls at the department of surgery of the university of Minnesota medical school. The prognosis of this condition is unfavorable. The occurrence of the characteristic triad of persistent and severe cyanosis, dyspnea, and failure to gain weight in an infant suggests the possibility of the presence of complete transposition of the great vessels. Angiocardiography, by injection of an opaque medium into a systemic peripheral vein, is very helpful in establishing the diagnosis of complete transposition. In 9 of the 29 patients angiograms were performed with no serious complications. Complete transposition is usually incompatible with a prolonged life unless an associated defect is present to allow some mixing of blood between the two basically separate pulmonic and systemic circulations. Infants most desperately ill have hearts with fewer associated anomalies and are, therefore, the best candidates for surgical treatment with an eventual goal of cure in this anomaly. The authors preferred an attempt to correct complete transposition of the great vessels anatomically by transposing all of the pulmonary veins and both venae cavae to match the abnormally reversed relationships of the aorta and pulmonary artery. Evidence is suggestive that patients with such a corrected circulation are physiologically normal and might anticipate a relatively normal life expectancy in the absence of other abnormalities. Of the 29 patients with complete transposition of the great vessels, 8 have been operated on. In the first four patients all of the right pulmonary veins were anastomosed to the right atrium. Two of these patients died and two survived, with both of the latter exhibiting significant objective and subjective improvement. This operation alone is not recommended unless large internal shunts are known to exist, because of the danger of inducing rapid heart failure in patients without adequate internal collateral shunts by unbalancing the systemic and pulmonic circulations. In four other patients, the inferior vena cava was shifted to the left atrium and the site of the cardiac end of the transected right pulmonary veins, the lung ends of which were anastomosed to the right atrium. None of these four patients survived. Because of these failures the authors believe that a previously prepared, but nonfunctioning, temporary and/or permanent preliminary shunt must be available so that once the blood flows from the pulmonary veins into the right auricle an appreciable amount of vena caval blood can be returned immediately to the left auricle in a compensating fashion. Their present plan, not yet tested, visualizes use of the azygos vein, canulated with as wide a bore polythene tube as it will accept, for shunting the blood from the superior vena cava into the tip of the right auricle.

Combined Adrenalectomy-Sympathectomy in Essential Hypertension.—Bilateral resections of the adrenal glands combined with bilateral sympathectomies of various types were performed on 29 women and 40 men between the second and sixth decades of life with severe arterial hypertension. The largest single group of patients had a removal of 95 to 98% of the total adrenal tissue, combined with a subdiaphragmatic sympathectomy and splanchnicectomy. It was found by experience that it was necessary to remove almost all of the adrenal tissue in order to obtain adequate reduction in blood pressures in most patients. There were two operative deaths, an operative mortality of 2.9%. Since operation nine additional patients died, making the over-all mortality 15.9%. Nine of the 11 patients who died were in group 4 of Smithwick's classification. Of the 69 patients, 21 obtained excellent results with postoperative blood pressures of 140/90 ± 10 mm. Hg in reclining and standing positions, 13 satisfactory results with blood pressure 140/90 ± 10 mm. Hg in standing position only, 28 continued to run elevated pressures but had improvement in symptoms and/or signs, and 7 were not benefited by the operative procedure. It is significant that 82% of the patients belonging to group 4 according to Smithwick's classification were benefited by the operation. A large number of these patients, who were previously considered unsuitable for sympathectomy alone, are now living and enjoying a more comfortable existence than they were before operation. Most of the patients with a favorable response in blood pressure require small daily doses of cortisone, desoxycorticosterone, and sodium chloride. The need for replacement therapy is best determined by the subjective symptoms of weakness and fatigue, which usually occur in advance of changes in blood chemistries. The need for close follow-up contact with these patients by a group entirely familiar with the patients and their backgrounds cannot be too highly emphasized.

Portal Venography Via Portal and Splenic Routes.—Roentgen definition of the normal anatomy of the portal venous bed was established by injecting 200 to 250 cc. of a thin barium sulfate mixture under minimal pressure into the superior mesenteric vein or inferior mesenteric vein of 50 fresh postmortem subjects in whom clinical and necropsy findings clearly excluded the possibility of portal hypertension. Thus roentgenograms of the portal venous bed were obtained which revealed three major anatomic types with respect to the relative position of splenic to portal vein; these have been designated as the tripod type, T type, and Y type. Anatomic variants with respect to the point of entry of the principal secondary tributaries entering the portal system were confirmed by the authors' roentgenographic studies as follows: The inferior mesenteric vein may join with splenic vein or the superior mesenteric vein, or enter in the crotch formed by the confluence of the splenic and superior mesenteric veins. The coronary vein also presents three varying points of entry, into the splenic or portal veins, or at the confluence of the two veins. As a result of these experiences, roentgen visualization of the portal venous bed at the time of operation is now routinely done in all patients with portal hypertension. Two techniques are used sequentially for operative portal venography: 1. The splenic portagram is accomplished prior to surgical incision, by the percutaneous injection of 40 to 50 cc. of a 70% sodium acetrizoate (Urokon sodium) solution into the splenic pulp through the ninth intercostal space. Laparotomy is then carried out through a short upper abdominal transverse incision. 2. In preparation for the portal portagram, the superior mesenteric vein is then isolated and canalized with a polyethylene catheter, and 40 to 50 cc. of a 30% sodium acetrizoate solution rapidly injected into the portal circuit within five to seven seconds. With the use of both types of roentgenograms operative portal venography has proved to be a valuable aid in the rational selection of portacaval or splenorenal shunt.

Portacaval Anastomosis for Portal Hypertension.—Of 25 patients with portal hypertension, all of whom had esophageal varices and gastrointestinal bleeding, 1 underwent splenectomy alone for congestive splenomegaly (Banti's syndrome), and 24 had a shunt operation, 17 for cirrhosis of the liver, and 7 for extrahepatic portal obstruction. Of the shunt operations, 14 were splenorenal anastomoses and 10 were portacaval of the side-to-side type. All patients survived the operation, and the follow-up period ranged from one to five years. The results of the shunt operations were rather disappointing in the patients with cirrhosis of the liver. Liver function tests did not show improvement in any patient but tended toward increased liver damage in all. Of the 17 patients, 9 derived temporary benefit in the regression of esophageal varices and cessation of gastrointestinal bleeding but relapsed and died within one year; 5 showed no improvement, and 3 remained well for more than one year. All of the deaths or relapses were accompanied by liver failure. Of the seven patients with extrahepatic portal obstruction, all were benefited immediately and in three the benefit was lasting. From this limited experience it appears that the portacaval shunt corrects only one of the factors responsible for bleeding from esophageal varices, and produces at best a temporary benefit. There is evidence that even partial deviation of the portal flow may impair liver function. Further experience is necessary before proper evaluation of portacaval shunts can be made.

Corticotropin and Cortisone in Cutaneous Diseases.—King and Livingood feel that, on the basis of experiences since the introduction of corticotropin and cortisone four years ago, it is possible to adopt certain general principles that serve as a guide in selecting patients for such treatment. Each patient must be considered individually. If the disease is a potentially fatal one (pemphigus, acute disseminated lupus erythematosus, or a severe drug sensitivity reaction), administration of corticotropin and cortisone is indicated and indeed mandatory even if contraindications exist, such as hypertensive cardiovascular disease, peptic ulcer, or psychosis. If the patient has a disease which is nonfatal, the physician is not justified in accepting the possibility of any type of complication by therapy, even if it may be presumed to be transient and of little consequence, for example, temporary hypertension and slight fluid retention. Before treatment with corticotropin or cortisone is instituted, a complete history and physical examination is necessary with particular emphasis on the presence of tuberculosis, peptic ulcer, and cardiovascular, renal, and neuropsychiatric disorders. A chest roentgenogram should be made, if indicated by the history or physical examination. Urinalysis is also essential. Statements with regard to specific dosages are impossible. Often doses for the same patient must be changed from day to day. The goal is the suppression of the acute manifestations of the disease as quickly as possible —this to be followed by reduction of the dosage to a minimum maintenance level, and if indicated, gradual withdrawal of the drug. For the majority of patients, the initial dosage is 300 to 400 mg. given in divided doses during the first 24 hours and followed by gradual reduction to a maintenance level of 100 mg. or less. Maintenance therapy is not necessary in self-limited dermatoses such as acute contact dermatitis and consequently the drug is withdrawn gradually in from 4 to 14 days. Patients who require maintenance therapy (acute disseminated lupus erythematosus, exfoliative dermatitis, and pemphigus) are generally managed more satisfactorily if the dosage of cortisone is not more than 75 mg. daily. A broad knowledge regarding all aspects of the management of cutaneous diseases is essential if the physician is to use corticotropin and/or cortisone appropriately and safely.

Influenza Virus Vaccine in Herpes Zoster.—Griswold and Bowen used an inactivated influenza virus vaccine in more than 250 patients with herpetiform conditions. This treatment was suggested to them by Swinny in 1949. They use a vaccine composed of equal parts of formalin-inactivated types A and B influenza virus prepared from the virus infected allantoic fluid of chick embryos. They inject 0.5 cc. subcutaneously as early as possible in the course of the disease and repeat this dose in 24 or 48 hours, and again, if necessary within another 48 hours. Of 100 patients with herpes zoster treated with the influenza virus, 63 patients were adjudged to have severe involvement, 30 moderately severe, and 7 mildly severe. The average number of injections was 2.64. Resolution of lesions manifested by drying of the vesicles and crust formation took place in 95% of the cases within 10 days. The outlook for satisfactory results was materially enhanced by the early administration of the vaccine. Patients who had the dermatological lesions for a week or longer and had neuralgic pain showed considerably less response than patients in whom the disease was of shorter duration. Influenza virus vaccine is valuable in herpes zoster, because it inhibits the appearance of new lesions, dries up old lesions, lessens pain in early cases, and reduces the incidence of postherpetic complications, although it appears to have no effect on postherpetic pain. The ease of administration, lack of side-reactions, and low cost of the treatment make it satisfactory for the ambulatory office patient. Herpes simplex also responds promptly to injections of influenza virus vaccine. Of about 150 patients with herpes simplex who received injections of influenza virus vaccine, 67% showed a response to one injection of the vaccine. Some patients who had recurrent episodes of herpes simplex were convinced that a series of five injections given at weekly intervals prevented the recurrent outbreaks for a period of seven to nine months, but permanent immunity apparently is not produced by this treatment.

Anticoagulant Therapy of Myocardial Infarction.—Despite the passage of eight years since the first introduction of the anticoagulants in the treatment of myocardial infarction, there is no unanimity of opinion concerning their value. This paper reviews the pertinent recent literature and draws some conclusions applicable for the average practitioner confronted with this problem. In two large hospitals, deaths caused by pulmonary emboli have risen in recent years, despite the widespread use of anticoagulants and vein interruption. The danger inherent in the administration of anticoagulants has not received due emphasis. The reported deaths from bishydroxycoumarin (Dicumarol) now exceed 100, and undoubtedly these are only a fraction of the actual number. During the period from 1948 to 1952 at the Johns Hopkins Hospital the author gained experience in the administration of bishydroxycoumarin to several thousand patients. There were no known fatalities caused by anticoagulants, and the system in use there could well be adopted by others. The prothrombin times were determined in a central laboratory and the bishydroxycoumarin therapy was ordered by the director of that laboratory and his assistants. Only a few persons with wide experience administered this therapy. Other anticoagulants with similar properties as bishydroxycoumarin have been introduced. The therapist should choose one agent and master its use. For maximum anticoagulant benefit for the first 48 hours, heparin should be used until bishydroxycoumarin becomes effective. The author concludes that anticoagulant therapy is not indicated routinely for the treatment of myocardial infarction, as good risk patients have no demonstrable need for it. Poor risk patients should receive these drugs according to present knowledge, although the final proof of their value is lacking. Bishydroxycoumarin should never be given in the presence of contraindications, in the absence of adequate control facilities, or by inexperienced therapists. Vitamin K_1 is an effective antidote and should always be available whenever bishydroxycoumarin is used.

Treatment of Incipient Apoplexy with Aminophylline Given Intravenously.—In a study of 12 hypertensive patients, to whom aminophylline was given intravenously, 9 patients with incipient apoplexy and 1 patient with transient angiospastic attacks were successfully treated. This study establishes for many cases the vasoconstrictor pathogenesis of cerebrovascular accident. According to this concept focal softening and possibly hemorrhage may be the final outcome of arterial vasoconstriction, which may in time cause irreversible structural damage to the nervous tissue by ischemia. Intravenously administered aminophylline immediately abolished all manifestations of apoplexy, coma, hemiplegia, and aphasia in the 10 successful cases, and in one of the two failures temporary improvement was noted. These results can be conceived of only in terms of the vasoconstrictor concept and are a new and decisive argument in favor of this interpretation. Euphylline (a proprietary preparation), one of the group of soluble theophylline preparations of which aminophylline is the prototype, was used in most cases.

Experimental Vascularization of Heart Muscle.—An attempt was made to improve the blood supply of the heart muscle of dogs by implanting vessels of the systemic circulation directly in the myocardium. In 10 animals, the internal mammary artery was implanted in the left ventricular wall, at a distance of about 1 cm. from the descending branch of the left coronary artery. The location in the left ventricle near the apex of the heart was selected because, according to experience, this is an area of predilection for infarcts. In addition, the descending branch of the left coronary artery supplies the largest area of muscles with blood. The effect of the vascularization experiments was tested after an interval of six to eight months. Indirect proof of sufficient vascularization was provided in two dogs by ligation of the left coronary artery and vein with a ligature near the origin of the descending branches of the two vessels; it did not result in a loss of contractility in the ischemic area of the pericardium in the course of a prolonged observation of the beating heart. Both animals survived the ligature of the descending branch of the left coronary artery without impairment of their general condition and work capacity. Satisfactory and continuous filling of the entire coronary system with the contrast medium on roentgenologic examination seven months after the implantation in five of six animals was considered direct proof of the communication of the internal mammary artery with the coronary vascular system. A contrast medium depot in the passage between the internal mammary artery and the coronary vascular system was considered a manifestation of newly formed blood vessels. Such communication could not be demonstrated in only one dog, and, consequently, obliteration of the mammary artery had to be considered; it was undoubtedly due to a technical fault. Further microscopic studies are necessary for a definite explanation of the genesis of the alternative blood supply to the myocardium. The histological aspects of numerous thin-walled, irregularly shaped vessels and capillary vessels in the abundantly indurated connective tissue that surrounded the implanted vessel corresponded to that observed in so-called organizing inflammation and recanalization. There seems to be no contraindication to the application of the authors' method of vascularization of the heart muscle to the human heart despite the considerable differences between the experimental surgical intervention on the normal heart of a dog and the therapeutic intervention on the heart of a patient with coronary sclerosis, as well as between experimental ligature of a branch of a coronary vessel and the arteriosclerotic vascular occlusion. The ischemic human heart muscle shows even a particular tendency to the formation of anastomoses.

Renal Adenoma.—According to Childs and Waterfall benign adenoma of the kidney requiring surgical treatment is not often reported, but each of them within a few months of each other, observed a case. A review of the literature disclosed that small adenomas of the kidney are seen not infrequently in routine postmortem examinations. The true incidence is difficult to determine; the smallest adenomas may escape detection because specific search is not made for them. The incidence of adenomas is equal in the two sexes but increases with increasing age. Reports of examination of large numbers of kidneys emphasize the association of adenomas with arteriosclerotic change in the kidney. The incidence of adenoma as well as carcinoma increases after middle life and parallels the incidence of vascular disease of the kidney. Adenomas may be barely visible to the naked eye, or they may reach the dimensions of the tumor described in one of the two cases presented here. The specimen, which consisted of a kidney and a large ovoid mass, weighed 2,470 gm. The presence of a mass in the case of larger tumors and hematuria in the smaller ones are the commonest presenting features. Pain may be present as an ache in the loin or as renal colic due to the passage of a blood clot. The diagnosis of renal tumor is made by intravenous and retrograde pyelography. Filling defect, distortion of calyces and renal pelves, and alteration in renal shadow may be seen. The diagnosis made will normally be that of carcinoma of kidney, but the even outline of the filling defect and possible smooth elongation of the calyces may arouse suspicion. The treatment of choice is nephroureterectomy because it is impossible to be certain that the tumor is not malignant. If it were possible to be sure of the diagnosis, then nephrectomy would suffice, and even successful partial nephrectomy has been reported. In the two cases presented, the tumors were large but neither was associated with heavy bleeding. Radiologically both specimens showed smooth filling defects, and in one case elongation of the calyces was noted. Both tumors were associated with hypertension of some degree, yet in neither case did the adjacent renal tissue show arteriosclerotic change. Histologically both tumors showed the solid structure that is usual in the larger specimens, and it is interesting that the largest of the two was essentially tubular in structure. Neither tumor showed any suggestion of malignancy, but either might well have undergone carcinomatous change had the cell type been less typical.

Approach to Psoriasis.—Psoriasis is a constitutional disorder expressive of disturbed adjustment between the patient and his environment. Allergic reactions may occur in psoriatic patients, but there is nothing to indicate that psoriasis is an allergic disease. Constitutional disorders tend to fall into groups, each characterized by a primary sphere of maladjustment. The maladjustment in psoriasis apparently involves the effect on the patient of his climatic environment. The incidence of psoriasis is highest among white persons living in temperate climates. Seasonal variation is common, and the condition is generally worse in winter than in summer. Secondary influences, which may be infective, endocrine, or nervous, are important in psoriasis, sometimes assuming the predominant etiological role. The condition, which occurs only in man, is primarily and essentially an epidermal reaction, and this fact may explain the importance of local therapy. Complete clearance of an eruption within two or three weeks is possible in almost every patient. The treatment used routinely at Leeds consists of a daily 10 minute bath in 20 gal. (75.6 liters) of water containing 4 oz. of a coaltar solution, followed by exposure after drying to an ultraviolet mercury vapor lamp, beginning with 30 seconds at 3 ft. (91.4 cm.), increased gradually as necessary to maintain a near-erythema dosage. A paste consisting of dithranol, 0.13 gm.; salicylic acid, 0.65 gm.; zinc oxide, 8 gm.; starch, 8 gm.; and soft paraffin (melting point 46 C) to 31 gm., is then applied to each lesion and allowed to dry. Talcum dusting powder may be used if desired. The patient is then covered with a stockinet sleeve dressing—vest, arms, and legs—after which he may dress and pursue his normal routine, returning in 24 hours for another treatment. Dithranol is an oxidizing agent, and it must be used judiciously to prevent irritation or burning of the normal skin. The zinc paste cannot be used on the scalp at any time but should be replaced with dithranol ointment B.P. or a pomade with mercury, salicylic acid, and tar, or both. Individual variations may be necessary in certain cases, but treatment must be continued until the skin is completely clear; not a single active lesion can be left if extension is to be avoided. Hospitalization is advisable, especially for a first course of treatment, but good results can be obtained even by modified home therapy. A daily bath with tar soap and regular care of the scalp are desirable as prophylactic and maintenance measures after the psoriasis has cleared.

Fatal Anaphylactic Shock Resulting from Penicillin.—The symptoms of sensitivity to penicillin are varied and range from a simple urticarial rash to severe and even fatal anaphylactoid reactions. A 31-year-old woman with bronchial asthma of 2½ years' duration, frequently associated with respiratory infection, was treated for four days in January, 1952, with penethamate (Estopen) hydrochloride, 500,000 units daily, and epinephrine (Adrenalin) hydrochloride as necessary. She had no unusual symptoms. She had a fresh respiratory infection accompanied by an attack of asthma in December, 1952. Treatment with penethamate was again instituted; the first injection of 500,000 units, given immediately after 0.5 ml. of 1:1,000 solution of epinephrine hydrochloride, was followed by a slight headache and a feeling of faintness, which passed in a few minutes. The second injection, consisting of 500,000 units accompanied by 0.75 ml. of hyperduric epinephrine given the next day, was followed five minutes later by pre- cordial pain lasting for several seconds. After this the patien appeared quite normal and conversed normally for another five minutes; then she suddenly collapsed and lost conscious- ness. Respirations became gasping and infrequent, and the woman died after a few minutes. A severe reaction on the first day may have been prevented by the simultaneous ad- ministration of epinephrine with the first injection, and the fact that slow-acting hyperduric epinephrine was given with the second injection may have allowed the fatal reaction to take place. Deaths resulting from penicillin hypersensitivit are fortunately very rare, but the possibility that fatal ac- cidents may occur should be emphasized. There is no pre- dictable pattern in penicillin hypersensitivity reactions—severa courses of penicillin may not give rise to symptoms befor and even after severe allergic reactions. Death may be cause by either crystalline or procaine penicillin, and careful inquir for signs of previous allergic phenomena should be mad before penicillin of any kind is repeatedly administered to an patient.

*Walking Test Before Decision on Mitral Commissurotomy. M. Lehmann and F. Karali.—p. 675.
Treatment of Gastroduodenal Hemorrhages of Ulcerous Origin. M. Girard. —p. 685.

Walking Test Before Decision on Mitral Commissurotomy.—Performance of the walking test serves as a check against the symptoms described by the patient. The test is simple and virtually without danger. It consists of a careful examination of the patient with regard to pulse rate, respiration, maximum breath holding, pulmonary auscultatory signs, and electrocardiogram recording. Next, the patient rapidly walks a 440 meter course having a 2.5 meter elevation. The test administrator accompanies the patient both going and returning and notes the time required for the entire trip and for each half. Finally there is a reexamination of the pulse rate, respiration, maximum breath holding, and pulmonary auscultatory signs. These are repeated every five minutes after a second new electrocardiogram has been made, until the patient returns to normal. When he has recovered, he is carefully interrogated as to the sensations experienced during the walking test. Responses of the 45 patients with mitral endocarditis tested were classified in four types: major tests (7 patients), in which pulmonary edema or hemoptysis appeared; clearly positive tests (13 patients), in which pulmonary auscultatory signs or fits of coughing appeared; feebly positive tests (13 patients), in which slight coughing and general disturbances appeared during the test itself; and negative tests (12 patients). Seven of this last group were operated on, on the basis of other evidence; six of them had mitral stenosis. These patients had not reacted normally to the walking test; it is to be hoped that further improvements in the test will enable it to incorporate these subtler symptoms.

Surgical Treatment of Spontaneous Subarachnoid Hemorrhage.—Spontaneous subarachnoid hemorrhages are caused by the rupture of intracranial aneurysms, and the patient's subsequent course, if he survives the initial accident, depends on the size of the rupture, the cessation, continuation, or recurrence of bleeding, and the extent to which the surrounding nervous tissue has been damaged. Recovery may be complete or may be accompanied by neurological sequelae. The most constant physical finding is neck rigidity not infrequently associated with bilateral Kernig and Babinski signs. The intense headache which usually precedes the hemorrhage is followed by impairment of consciousness, varying from slight clouding to deep coma, and perhaps a few epileptiform fits. The finding of uniformly blood-stained cerebrospinal fluid on lumbar puncture will confirm the diagnosis. An intracranial aneurysm should be suspected when a patient presents certain clinical syndromes, notably (1) oculomotor nerve palsy associated with severe supraorbital pain; (2) bilateral hemianopia with intense headaches and a normal sella on x-ray examination; or (3) unilateral blindness in the absence of any local disease of the eye. Discovery of an intracranial aneurysm before rupture has occurred should lead to prompt institution of treatment, because it is impossible to say just when the bursting point will be reached. Conservative treatment is sometimes successful, but when a patient has survived an initial hemorrhage, he should be examined angiographically as soon as his condition permits; if an aneurysm is found on the carotid system, surgical treatment should be seriously considered. The choice of treatment, either arterial ligation in the neck or a direct intracranial attack on the aneurysm itself, will depend on the position of the aneurysm, the efficiency of the anastomotic circulation, and the patient's general condition. The presence of an intracranial aneurysm was demonstrated in 28 patients seen by the author; of these, 24 were treated surgically, 23 by carotid ligation and one by a direct attack. Six of the 24 patients died; three were in a desperate condition and might have been refused operation, one had a massive aneurysm beyond the scope of surgical cure, one had an abnormal circle of Willis with unsuspected atheroma, and only one died as a result of recurrent hemorrhage. Eighteen of the surviving patients are leading useful lives; one is recovering from hemiplegia, one, who is clinically well though idle, is considered untrustworthy, and in only one does incapacity appear to be permanent.

berg's lymphog association, cervical,
axillary and in appear early. The diagnosis of pulmonary cryptococcosis is made by isolating the causative organism in the sputum of the patients, preferably from secretions obtained by bronchial aspiration. The authors report three fatal cases of pulmonary cryptococcosis in patients with a clinical and histopathologic diagnosis of Hodgkin-Sternberg's lymphogranulomatosis. Cryptococcus neoformans (Torula histolytica) was isolated from the sputum of the three patients. In the only case in which a necropsy was made, C. neoformans was isolated from the lymph nodes, the bone marrow, the lung, and the spleen. Pulmonary cryptococcosis should be considered in the differential diagnosis of pulmonary and lymph node diseases of obscure origin and also as a probable associated or causal disease of Hodgkin-Sternberg's lymphogranulomatosis.

- Physiological Bases of Amino Acid Metabolism and Their Significance in Therapy. H. Berger.—p. 761.

"Swing-Therapy" of Pulmonary Tuberculosis.—A new form of chemotherapy, the so-called swing-therapy, has been suggested for the treatment of pulmonary tuberculosis. An intermittent course of *p*-aminosalicylic acid and streptomycin for two months is followed by a one month course of isoniazid combined with *p*-aminosalicylic acid; streptomycin is administered intramuscularly in doses of 1 gm. on one of three days; isoniazid is given daily by mouth in doses of 5 mg. per kilogram of body weight; on two of three days, *p*-aminosalicylic acid is given by mouth in doses of 10 to 12 gm., or occasionally by infusion in doses of 20 gm. daily. Of 168 patients with pulmonary tuberculosis, 41 were given this "swing-therapy"; 59 received isoniazid alone, 23 were given combined treatment with isoniazid and *p*-aminosalicylic acid and 45 intermittently received *p*-aminosalicylic acid and streptomycin. Duration of treatment varied from three to eight months, and only that of "swing-therapy" up to 10 months. Comparison of observations in these four groups of patients showed that clinical, bacteriological and roentgenologic results obtained with "swing-therapy" were better than those with combined streptomycin and *p*-aminosalicylic acid treatment or with combined isoniazid and *p*-aminosalicylic acid treatment. Especially recent, dense extensive infiltrations showed definite regression. Periodical alternation of streptomycin and isoniazid with *p*-aminosalicylic acid as the basic drug proved reliable in preventing the occurrence of dr

Nervous Mechanism of Sensitization Eczema.—Contact eczema is primarily not an epidermal but a dermal syndrome; it is a vascular process in which the reaction begins with vasodilatation and progresses through inflammatory edema of the dermis, with secondary infiltration of the basal layer of the epidermis, which may or may not result in the formation of vesicles of varying size and location. Numerous experiments have been performed to show that contact eczema can appear only when the circulation of the blood and lymph is intact, but these experiments do not take into account the integrity of the nerve supply, which may also explain the results obtained. Study of the part played by the nervous system in the production of sensitization and in the precipitation of eruptive attacks in sensitized persons shows that the vesicular syndrome is the response of a central reflex set in motion by any bipolar irritation of a sensitive pathway. Experiments with guinea pigs proved that the presence of a chemical allergen on the skin in contact with the peripheral sensitive endings and the simultaneous application of the same allergen to the posterior ganglion sets up a specific bipolar irritation which immediately produces a vesicular eczematous syndrome. The same mechanism is responsible for the vesicular syndrome of herpes zoster. Ordinary, nonexperimental application of a chemical substance to the skin in conditions assuring its penetration results in transmission of the allergen to the ganglion by way of the nerves, and the time required for sensitization is the time it takes to complete the transfer. Once the bipolar irritation has been set up, it remains latent for a long time, reappearing in the form of fresh attacks of eczema whenever nonspecific central or even peripheral excitation of sufficient intensity occurs. The close connection between the surface of the skin and the sensitive pathways revealed by these experiments should throw new light on various other syndromes affecting the skin.

Relapse in Pulmonary Tuberculosis After Effective Operative Collapse Treatment.—In the follow-up of 537 patients from 3 to 14 years following successful collapse treatment by thoracoplasty or extrapleural pneumothorax, 131 relapses were registered—61 among the 216 thoracoplasty patients and 70 among the 321 extrapleural patients. *Seip estimates* that milder or more serious recurrences of the pulmonary tuberculosis are to be expected within 10 years after operation in about one-third of the patients effectively treated by these methods and within 15 years in about half the patients. The frequency of relapse does not decline noticeably from year to year as far as the examination has gone. Fatal relapses and relapses not cured to date were more frequent after thoracoplasty than after extrapleural pneumothorax. With both methods most of the relapses were in the untreated lung. In case of relapse the prognosis was better in the cases with small and moderate cavities in one apex and relatively more healthy lung tissue. In the long run recurrence of the pulmonary tuberculosis represents the greatest danger to these patients, and every effort should be made to save as much as possible of the pulmonary function. The main point in favor of extrapleural pneumothorax in collapse therapy is that it causes less interference with the pulmonary function.

*Raw Egg Yolks as Supplement to Roentgen Treatment of Osteogenic Sarcoma in Children (Patients Under 18) from May 1, 1950, to May 1, 1952. C. Krebs.—p. 1107.

Raw Egg Yolks as Supplement to Roentgen Treatment of Osteogenic Sarcoma in Children.—Sarcomas of the bone usually start in the metaphysis or diaphysis, and, although they can penetrate muscles, fascia, vessels, and skin, they rarely advance beyond the epiphyseal line. For years Krebs has tried various methods for arresting the growth of these tumors, but of 32 patients treated in the 14 years up to May, 1950, none are living. Since that time he has supplemented roentgen treatment with the administration of eight raw egg yolks daily on the assumption that fresh raw egg yolks contain the necessary growth hormones. Possibly to increase calcium deposit, regarded as a factor in the healing process, the eggs used are from hens fed daily on common meal. The seven cases thus treated, in patients aged from 8 to 16, are described in detail. The average length of life for these patients is at least 626 days, and the survival time of three of the patients exceeds the life expectancy by more than four times the average expected.

*Experiments with Hepatitis Virus. G. Wildführ.—p. 573.
Study of New Method for Influencing Erythrocyte Sedimentation Rate with Lithium-Carmine. D. Schmidt-Ramsin.—p. 581.
Treatment of Leukoses in Children with Cortisone and Corticotropin (ACTH). J. Oehme.—p. 591.
Chronic Cor Pulmonale Secondary to Pulmonary Embolism. K. Bobek and J. Vaněk.—p. 596.

Experiments with Hepatitis Virus.—The serum and the bile obtained from 169 patients with hepatitis were injected into hamsters or in hamsters and simultaneously in canary birds, green finches, or siskins. In parallel experiments serum and bile of patients with hepatitis were inoculated in chicken eggs, which had been incubated previously for 10 days and were incubated again for four days after the inoculation. Results showed that the infectious agent was transmitted from 26 of the 169 patients to hamsters alone, and from one patient to the chicken embryo alone; simultaneous transmission of the infectious agent from 8 patients occurred in hamsters and canary birds, and from 17 patients in hamsters and chicken embryos. In addition, positive results were also obtained with the passage of the chorioallantois, which had shown mild opacification, or with the sterile filtrate of pulverized, pathologically changed chicken embryo livers to incubated chicken eggs or to hamsters, and from hamsters back to chicken embryos. Certain irregularities in these experiments may depend on variation of resistance to the virus in the animals experimented on. Microscopic examination of the liver of the experimental animals and of the chicken embryos always showed the same changes among which necrosis was an important symptom. In the passage experiments, the incubation period was frequently shortened, but occasionally a prolonged incubation period was observed. These phenomena may have been caused by variations in the virulence of the pathogenic agent. A sudden stop of the passages was not a rare occurrence. *Absorption tests* with convalescence serums and viruses obtained by passage revealed the occurrence of several serologic types of the hepatitis virus: one type for the serogenous form of hepatitis; and at least two types for the epidemic hepatitis. Additional serologic types may be considered. Photographs made with the aid of the electron microscope of the *sterile, pathologically* changed liver *filtrates* showed small round corpuscles, 35 to 50 mμ in size. The same material proved to be infectious in animal experiments and specific in the absorption test.

BOOK REVIEWS

Dermatology in General Practice. By Jacob Hyams Swartz, M.D., Assistant Professor of Dermatology, Harvard Medical School and Post-Graduate School, Boston. Foreword by C. Guy Lane, M.D. Cloth. $11. Pp. 581, with 253 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

This book is intended for the general practitioner and serves well the purpose for which it was prepared. In it can be found excellent black and white illustrations; detailed information on clinical picture, etiology, differential diagnosis, and treatment that is offered in brief but informative style; and general discussions that provide a wealth of material sometimes overlooked in more didactic presentations of this subject. For example, there is a brief review of the anatomy of the skin, its physiology, and metabolic considerations. There is also a discussion of the care of normal as well as abnormal skin, and of the diseases of the hair and scalp, face, trunk, and other parts of the body. The reader who wonders about the care of the feet, hands, or face, the effect of sun exposure, the care of a wrinkled skin, the role of cosmetics, or the care of the baby's skin may find answers to his questions in this volume. There is an ample index, the type is plain and easy to read, and the size of the volume makes it handy to use.

The Ballistocardiogram: A Dynamic Record of the Heart Beat. By John R. Braunstein, M.D., Ph.D., Associate Professor of Biophysics and Assistant Professor of Medicine, University of Cincinnati, Cincinnati. Publication number 143, American Lecture Series, monograph in American Lectures in Circulation. Edited by Irvine H. Page, M.D., and A. C. Corcoran, M.D. Cloth. $3. Pp. 84, with 41 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This monograph records two lectures delivered by Dr. Braunstein at the University of Cincinnati in 1951. The major portion of this book is concerned with physical principles of the ballistocardiogram and its physiological applications. There is a brief description of the abnormal ballistocardiogram and its relation to disease. The theory of the vector ballistocardiogram and design and construction of the instrument are discussed with diagrams in a short chapter. There is also an appendix in which some of the physical and mathematical constants of the instruments used are discussed in some detail. A short bibliography containing the important references in the field is given at the end of the book. This monograph is a good reference book for those already familiar to some extent with the subject of ballistocardiography.

Die Ostitis deformans Paget. Von Dozent Dr. med. habil. W. Hirsch, Oberarzt der medizinischen Universitätsklinik Leipzig. Cloth. 22 marks. Pp. 216, with 92 illustrations. Georg Thieme, Thomaskirchhof 21, (10b) Leipzig C 1, 1953.

Hirsch reports the results in a series of 136 patients with osteitis deformans (Paget's disease). Because this condition is still overlooked and erroneously classified as rheumatism, the appearance of this monograph is timely. Hirsch brings out that von Recklinghausen's views and Paget's views have been described by Engel and the findings attributed to one common disease, a concept that unfortunately found wide recognition. In his opinion not only is this an incorrect deduction but it represents retrogression as far as knowledge of this malady is concerned. He goes into great detail in correlating the clinical, roentgenologic, and pathological-anatomic studies of Schuchardt, Sternberg, Kienböck, Looser, and Schmorl. After a thorough evaluation of these studies, he is convinced that the osseous changes described by Paget and by Engel represent two basically different and distinguishable diseases. That the debate over the nature of osteitis deformans has not been closed is emphatically expressed. The theories regarding an inflammatory cause and the part played by primary vascular changes are admirably analyzed.

Hirsch has attempted to study the diagnostic problems of osteitis deformans in the light of functional and dynamic considerations not only from a theoretical point of view but also on the basis of his own studies. It is this latter fact which gives this presentation its greatest value. This work is mainly speculative and tries to correlate previous and modern knowledge. The literature is adequately and thoroughly covered. The reports on his personal series are flawless. For those interested in the chemical, cytological, histopathological, and roentgenologic aspects of this disease, this book will prove most illuminating. It is both a didactic as well as a philosophical approach to this still unexplained condition.

Atlas of Regional Dermatology. By Ernest K. Stratton, P.D., M.D., Research Associate, George Williams Hooper Foundation for Medical Research, University of California Medical Center, San Francisco, et al. Cloth. $15. Pp. 274, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book should appeal to all practitioners as well as to dermatologists, for the material is arranged by regional groupings, an arrangement that is useful for purposes of differential diagnosis. There are, for example, 22 illustrations of different scalp lesions, both common and unusual diseases, and 12 each of diseases of the lip and ear. Also grouped together are lesions of the upper limb, lower limb, face and neck, nails, mouth, and lip. In addition, there are special chapters devoted to leprosy and to the exanthems. A brief account of the etiology, symptoms, diagnosis, and treatment accompanies most of the illustrations. Of the 596 photographs, only 25, grouped into 7 figures, are in color; these are small but most of them are good. The others, of larger size in black and white, are as excellent as such illustrations can be. The pages are large, 8½ by 11 inches, on heavy glossy stock. There is a complete index. It is evident that an immense amount of effort went into the collection and selection of this group of photographs, and Stratton's statement that the book is intended primarily for the student who requires visual help in identifying skin diseases has been fulfilled.

Introduction to Medical Science. By Gulli Lindh Muller, M.D., Assistant Research Physician, Thorndike Memorial Laboratory of Boston City Hospital, and Dorothy E. Dawes, R.N., M.A., Science Instructor, Schools of Nursing, Greater Boston. Third edition. Cloth. $4.75. Pp. 610, with 114 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

The purpose of this book is to provide for the student nurse an over-all view of medical science prior to clinical instruction on the wards. Beginning with an outline of the history of medical progress, the authors proceed to discuss the role of the nurse in relation to the causes and manifestations of disease, methods of diagnosis, bases for treatment, preventive measures, and methods of control. Several chapters from the earlier edition have been completely rewritten, and additional information has been added on recent advances in medical science. New topics include recently isolated hormones, [illegible] function tests, radiation syndrome and the use of isotopes, recent advances in the therapy of mammary and prostatic cancer, the treatment of leprosy, surgery of the heart, the latest information on use of the antibiotics and the vitamins, and geriatrics. The discussion of public health agencies, including government organizations promoting health and welfare, has been brought up-to-date. New information has been added on sanitary conditions in the home and on other preventive medicine subjects. The book is clearly and concisely written and emphasizes the fundamental principles of medical science that will enable the nurse to make the proper adjustment to the needs of the patient, the physician, and the community.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

Nervous Mechanism of Sensitization Eczema.—Contact eczema is primarily not an epidermal but a dermal syndrome; it is a vascular process in which the reaction begins with vasodilatation and progresses through inflammatory edema of the dermis, with secondary infiltration of the basal layer of the epidermis, which may or may not result in the formation of vesicles of varying size and location. Numerous experiments have been performed to show that contact eczema can appear only when the circulation of the blood and lymph is intact, but these experiments do not take into account the integrity of the nerve supply, which may also explain the results obtained. Study of the part played by the nervous system in the production of sensitization and in the precipitation of eruptive attacks in sensitized persons shows that the vesicular syndrome is the response of a central reflex set in motion by any bipolar irritation of a sensitive pathway. Experiments with guinea pigs proved that the presence of a chemical allergen on the skin in contact with the peripheral sensitive endings and the simultaneous application of the same allergen to the posterior ganglion sets up a specific bipolar irritation which immediately produces a vesicular eczematous syndrome. The same mechanism is responsible for the vesicular syndrome of herpes zoster. Ordinary, nonexperimental application of a chemical substance to the skin in conditions assuring its penetration results in transmission of the allergen to the ganglion by way of the nerves, and the time required for sensitization is the time it takes to complete the transfer. Once the bipolar irritation has been set up, it remains latent for a long time, reappearing in the form of fresh attacks of eczema whenever nonspecific central or even peripheral excitation of sufficient intensity occurs. The close connection between the surface of the skin and the sensitive pathways revealed by these experiments should throw new light on various other syndromes affecting the skin.

Dermatologic Formulary. Frances Pascher, M.D., editor. From New York Skin and Cancer Unit, Service of Dermatology. (Dr. Marion B. Sulzberger, Director). Revised edition. Cloth. $3. Pp. 150. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

This pocket-sized book is arranged in three sections: topical remedies, systemic therapy, and articles for clinic use such as cauterizing agents, biologicals, and local anesthetics. This comprehensive formulary is designed to meet the needs of a large dispensary and includes not only the time-tested older remedies but a large number of the newer preparations including steroids. With each prescription there are explanatory notes of the action and use of the drug, the disease for which the drug is indicated, directions for its use, and contraindications. Examples of all types of medicaments are included, and, when necessary, both the scientific and proprietary names are listed. It is a selected formulary, so that only four antihistaminic preparations, two superfatted soaps, and four antibiotics are included. The index lists, in addition to the drugs, the commoner disease entities and remedies for them. Altogether, it is a useful compilation that should be a great help in prescribing for dermatological diseases.

The Green and Red Planet: A Physiological Study of the Possibility of Life on Mars. By Hubertus Strughold, Professor of Aviation Medicine, Head of Department of Space Medicine, U. S. Air Force School of Aviation Medicine, Randolph Field, Texas. With editorial assistance and foreword by Green Peyton. Cloth. $4. Pp. 107, with illustrations. University of New Mexico Press, Albuquerque, New Mexico, 1953.

Strughold considers in detail the almost boundless versatility of living things and summarizes with equal care the mass of data now available as to the temperatures, pressures, and chemical situations existing on the surface of Mars. He concludes that life of an order comparable to ours is impossible on Mars or on any other known planet of our solar system. It is extremely probable that the conditions that permit life on our earth are closely duplicated in other places in the universe, but at distances so great that signals, traveling even with the speed of light, cannot reach them and be returned within the span of a human lifetime. While this paradox gives a tantalizing note to the author's theme, his analysis of the physiological problem will interest many medical readers.

Criteria for Retirement: A Report of a National Conference on Retirement of Older Workers. Editor: Geneva Mathiasen, Secretary, National Committee on Aging. Held at Arden House, Harriman Campus of Columbia University, January 24-26, 1952. Under sponsorship of McGregor Fund and National Committee on Aging of National Social Welfare Assembly. Cloth. $3.50. Pp. 233. G. P. Putnam's Sons, 210 Madison Ave., New York 16, 1953.

About 70 experts from government, business, unions, public health, social work; and universities participated in the conference of which this volume is the report. Part 1 of the book summarizes the purpose, discussions, and recommendations of the conference, and part 2 contains three monographs written for the convenience of the participants. The first, "Retirement from the Point of View of the Worker," was written by a faculty committee of the Graduate School of Public Health of the University of Pittsburgh; Harland Fox, research fellow of the Industrial Relations Center of the University of Minnesota, contributed "Responsibilities of Employers, Workers, Unions, and Government"; and "Economic Problems of Retirement" was prepared by Sumner H. Slichter, Lamont Professor of Economics at Harvard University. Three speeches given at the conference (by C. P. Cochrane, Industrial Relations Director of Eastman Kodak Company; Harry Becker, Associate Director of the Social Security Department of the UAW-CIO; and Theodore Klumpp, M.D., president of Winthrop-Stearns, Inc.) form part 3 of the volume.

The stated purpose of the conference was to discover some criteria other than chronological age for continued employment of older workers. Included in the large amount of information gathered to evaluate and explore the problem were factual data on age and population trends, income, employment, and retirement policies; professional opinions on the social, psychological, and physiological aspects of aging and retirement; the methods, advantages, and hazards of employing older workers; the administrative problems of retirement; and the effect of the employment or retirement of older persons on the national economy. The conference and this book are attempts to present and integrate data and opinions from many fields of experience and various points of view, as they bear upon the problems of our aging population. The scope and factual richness of this report present contributions on a subject that has been of increasing concern to us all. The broad conclusions of a majority of the participants were that all interests concerned would profit if older persons worked as long as they were willing and able; that an arbitrary upper age limit for retirement should be set high enough to affect very few workers and, in an age range below this, health and competence should determine retirement decisions; and that the plant physician and union and management representatives should make retirement decisions jointly.

Of special interest to physicians are sections on physiological age versus chronological age; physiological age and job performance, and the value of health records accumulated over the years in assessing the proper time for retirement.

Rudolf Virchow: Doctor, Statesman, Anthropologist. By Erwin H Ackerknecht. Cloth. $5. Pp. 304, with 3 illustrations. University of Wisconsin Press, 811 State St., Madison 5, 1953

This book is the first full-length study of a remarkable 19th century personality whose influence dominated three spheres of activity. First, as a 30-year-old pathology professor, Rudolf Virchow proposed the concept, later termed "cellular pathology," that the basic units of life are the self-reproducing cells of living bodies and that pathology primarily has to concern itself with cell changes. Second, as a politician, he served for more than 40 years in the Prussian parliament as one of the militant opposition leaders against Bismarck and was one o the symbols of a liberal Germany until death intervened Finally, as an anthropologist, Virchow systematically studied the physical characteristics and culture of the German people and offered concrete evidence to deny the myth of Teutonic supremacy. In addition, his medical interests stimulated him to engage in a reform movement that produced modern sanitation, school reforms, and the hospital system currently in use today. This book is recommended to all readers who are interested in learning of the achievements of a man of unusua intellectual powers, personal integrity, and courage.

An Atlas of the Commoner Skin Diseases. By Henry C. G. Semon M.A., D.M., F.R.C.P., Consulting Physician for Diseases of Skin, Roya Northern Hospital, London. Colour photography originally directed by the late Arnold Moritz, B.A., M.B., B.C. Fourth edition. Cloth. $13.50 Pp. 370, with 147 plates reproduced by direct colour photography from living subject. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; [John Wright & Sons, Ltd., 42-44, Triangle West Bristol 8, England]; 1953.

This atlas is replete with photographs in color and brie descriptions of what may be seen in the illustrations. It is no as complete as some texts because it does not provide details of diagnosis, etiology, and treatment. It does offer, however some remarkably outstanding colored photographs that will be of great help to the practitioner and student, particularly i he does not see some of the conditions very frequently. The descriptions of the disease and treatment are offered in capsule form, but this in no way detracts from the usefulness of the volume. It is a worthwhile addition to any library and should be as useful to the general practitioner, the student, or the pediatrician as to the dermatologist. The book is well bound the paper is of good quality, and the type is pleasing to the eye.

Progress in Neurology and Psychiatry: An Annual Review, Volume VIII. Edited by E. A. Spiegel, M.D., Professor and Head of Department of Experimental Neurology, Temple University School of Medicine, Philadelphia. Cloth. $10. Pp. 591. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

Continuing the pattern adopted in previous editions, this annual review of the literature is presented in four parts dealing with basic sciences, neurology, neurosurgery, and psychiatry. The chapter headings are the same as those used in the 1952 edition with the following exceptions: In section 2 the chapter on neurosyphilis has been omitted (neurosyphilis does not even appear in the index), and a chapter on neuro-ophthalmology and another on clinical electromyography have been added; in section 3 the chapter on the vascular system has been replaced by a chapter on the surgical treatment of pain and motor disorders; and in section 4 the chapter on genetics in neurology and psychiatry has been replaced by one on alcoholism. Those who have found the previous volumes useful will want to add this one to their libraries. Nonspecialists will find it a valuable reference work because of its wide scope and extensive bibliography.

Heredity in Health and Mental Disorder: Principles of Psychiatric Genetics in the Light of Comparative Twin Studies. By Franz J. Kallmann, M.D., Principal Research Scientist (Medical Genetics), New York State Psychiatric Institute, New York. With foreword by Nolan D. C. Lewis, M.D. Cloth. $6. Pp. 315, with 89 illustrations. W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1953.

This book succinctly summarizes evidence for the genetic basis of health and mental disorder. It is based on the three lectures of the 19th series of the Thomas W. Salmon Lectures, which Dr. Kallmann, eminent for his research on the inheritance of schizophrenia, was invited to give. The present book brings together the results of Dr. Kallmann's 16 years of research for the New York State Psychiatric Institute, involving not only the genetic basis of schizophrenia but also many other psychiatric diseases. The first part of the book, "Heredity in Relation to Mental Health," is an excellent review of the general principles of genetics and their historical development, though it may be difficult reading for those who have never had a beginning course in genetics. In order to investigate the part played by heredity in disease, Dr. Kallmann has studied thousands of pairs of twins, of both the monozygotic or identical inheritance type and the dizygotic or different inheritance type. Profuse use of pictures of the twins throughout the book enlivens the material. The second part of the book, "Heredity and Mental Disorder," gives evidence for the hereditary basis of psychoneurotic and delinquent behavior, deficient resistance to stress and infection, pathological sex variants, psychotic reaction types of all kinds, convulsive diseases, neurological disorders, and mental deficiency.

In the last section, Dr. Kallmann applies the results of genetic research to mental health planning. Correcting common misconceptions regarding the role of heredity, Dr. Kallmann dispels the fear that, because a hereditary basis for disease is found, one must be pessimistic regarding treatment, by citing hormonal treatment for eunuchoid condition and insulin for diabetes. Nor does the existence of a genetic factor in psychiatric illnesses minimize the psychodynamic significance of unfavorable environmental influences that may have precipitated the illness in genetically predisposed individuals. The constructive use of research in human genetics as differentiated from pseudoeugenic fanaticism is described in marital counseling and other situations.

Fool's Haven. By C. C. Cawley. Cloth. $2.75. Pp. 210. House of Edinboro, Publishers, 21 Edinboro St., Boston, 1953.

This is a short, fast-moving story of a college student and his fiancé, the daughter of a member of a religious sect that believes in faith healing and forbids any reliance on medical care. "One can not have both God and a doctor," the self-ordained pastor of this sect is quoted as saying. The story is probably not lasting prose, but it raises what may be a lasting question, namely, the right of society to interfere with a person's religious beliefs when those beliefs deny to a sick person proper medical attention. The student is amazed when he discovers that his future mother-in-law will not allow her son to be given Pasteur treatments after he was bitten by a rabid dog. He is, of course, irate but powerless to intervene. When his fiancé dies of acute appendicitis without having been offered the advantages of proper medical care and hospitalization, her mother is found guilty of manslaughter. The student's satisfaction over this fact is marred because the mother is paroled without serving even one day in jail and the pastor who urged her to act as she did is acquitted. It is difficult to view the question raised by this little book impartially, and it is quite likely that all who read the book will be angry. The faith healers will be angry because of the disbelief of others, who in turn will be angry because of the blind and unrealistic attitude of the faith healers. Regardless of one's beliefs, however, the question is fairly well presented and should stimulate many an informal discussion on the subject.

Psychosomatic Approach to Gynecology and Obstetrics. By Fritz Wengraf, M.D., Adjunct Neuropsychistrist, Beth Israel Hospital, New York, New York. Publication number 164, American Lecture Series, monograph in Bannerstone Division of American Lectures in Gynecology and Obstetrics. Edited by E. C. Hamblen, B.S., M.D., F.A.C.S., Professor of Endocrinology, Duke University School of Medicine, Durham, N. C. Cloth. $6.75. Pp. 346. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book, written by a neuropsychiatrist, was designed to supplement texts on gynecology and obstetrics and to further the interest of obstetricians and gynecologists in a psychiatric approach to their work. Since the author does not use the highly technical terminology of psychoanalysis, physicians who are not specialists in psychiatry and psychoanalysis will find it easy to read. The book is divided into six sections on (1) functional disorders; (2) constipation; (3) minor gynecology, covering puberty, dysmenorrhea, psychosomatic uterine bleeding, functional amenorrhea, psychogenic leukorrhea, frigidity, and the menopause; (4) operative gynecology, including preoperative care of neurotic patients, postoperative neurosis, and anesthesia; (5) obstetrics, including gestation, parturition, confinement, lactation, and abortion; and (6) psychotherapeutics, treating the gynecologist's significance to woman's unconscious and methods of psychotherapy.

There are 50 illustrative case reports distributed throughout the book. At the end is an extensive bibliography of 516 references, and all the authors of these references are quoted at least once in the text. This book is well written, and the publishers, too, have done their part well. Obstetricians and gynecologists will find a considerable amount of instructive and interesting material in this book.

Health Principles and Practice. By C. V. Langton, B.S., M.S., Dr.P.H., Director of Physical Education, Oregon State College, Corvallis, and C. L. Anderson, B.S., M.S., Dr. P. H., Professor of Hygiene and Health Education, Oregon State College. Cloth. $4.25. Pp. 417, with 47 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1953.

This is a college textbook for courses in health or hygiene. It has been designed by the authors to provide those who will be community leaders with "an appreciation and basic understanding of hygiene both from the standpoint of its contribution to personal health as well as the effect this knowledge may have if applied properly to the community in which they live." It presupposes an elementary understanding of body structure, function, and other aspects of human biology and deals directly with personal and community health interests in concepts and vocabulary on a college level. Excellent chapters give accepted views on heredity and eugenics, nutrition, exercise, fatigue, rest, air and sunlight, poisons, and personal care. The chapter on mental health includes a discussion of the development of a well-adjusted personality and suggestions for promoting mental health as well as the usual description of classical disorders. Sex and reproduction are covered in franker detail than is customary in a book of this type. A general view of community health is covered by chapters on international and national health services, state and local health services, and communicable disease control, and by a statistical discussion of changing concepts and approaches in the field of health.

In general this is a sound supplement to a college course on personal and community health. Items may need clarification or expansion by the instructor, and there will be differences of opinion on the administration of certain health programs. Nevertheless this book shows evidence of being written by an educator well versed in the subject of health.

Stedman's Medical Dictionary of Words Used in Medicine and Their Derivations and Pronunciation Including Dental, Veterinary, Chemical, Botanical, Electrical, Life Insurance and Other Special Terms; Anatomical Tables of Titles in General Use, the Terms Sanctioned by the Basle Anatomical Convention; the New British Anatomical Nomenclature; Pharmaceutical Preparations Official in the U. S. and British Pharmacopœias or Contained in the National Formulary; Biographical Sketches of the Principal Figures in the History of Medicine. Edited by Norman Burke Taylor, V.D., M.D., F.R.S.C., in collaboration with Lieut. Col. Allen Ellsworth Taylor, D.S.O., M.A. Eighteenth edition with etymologic and orthographic rules. Cloth. $11.50. Pp. 1561, with illustrations. Williams & Wilkins Co., Mt. Royal and Guilford Aves., Baltimore 2, 1953.

Reflecting the growth of medical knowledge, this 18th edition of "Stedman's Medical Directory" has 200 more pages than the 17th edition issued in 1949. Several thousand words and nearly 600 new illustrations have been added. The useful appendixes indicated by the subtitle have been continued, and others have been added, such as tables of pathogenic organisms, of weights and measures, and of standard weights according to height and age. The finished product, however, portrays the unresolved conflict between current usage, editorial preferences, and a sheer inertia that retains many terms long past their usefulness. Current usage is satisfied by inclusion of such compounds as "isonicotinic acid hydrazide," "2,3-dimercaptopropanol" (Dimercaprol), and para-aminosalicylic acid," as well as "adrenocorticotrophic hormone" (ACTH) and "17-hydroxy-11-dehydrocorticosterone" (cortisone). The editors' preference is expressed not only in the preface where they discuss "etymological miscegenation" but in their permitting such remarks as this under "sulfapyradine": "It is called dagenan and unfortunately M and B 693." Surely only inertia can be responsible for the continued inclusion of such terms as these: nephrauxe, nephremia, nephria, nephrism, nephrocapsectomy, nephroerysipelas, nephroptosia, and nephroscleria. Acid is given one column with its subheads, and, for some unexplained reason, acidum is given nearly four.

Unexplained, too, is the cross from sulfoxone sodium (the generic name) to Diasone (the proprietary); the widely variant definitions of acid, ascorbic, and ascorbic acid and of acid, chondroitic, and chondroitic acid; the use of neither cross reference nor definition under Ballance operation for the Koerte-Ballance operation; and putting sigma reaction under "S" but not under "Reaction." Most of the anatomical terms previously given in Latin have been translated into their English equivalents, but many other nouns keep their Latin endings. Thus "sulfanilamide" is used in the definition of "sulfa drugs" but under sulfanilamide itself there is only the cross reference "See Sulfanilamidum (U. S.)." Proofreading errors sometimes occur, as in the 11-line definition of Schwann's sheath, which contains three glaring misspellings, and in the filing of a well-known phenomenon under Schwartzmann instead of Shwartzman as used in the "A. M. A. Directory" and "Who's Who." Destructive criticism, however, is always easy and is necessarily somewhat unjust in appraisal of a monumental work of this sort. Amassing and organizing the medical vocabulary within a scholarly framework such as this is an achievement of no mean order, and one of value to anyone needing such a dictionary.

Zwang und Freiheit in der Erziehung: Erziehen, Strafen, Reifenlassen. Von Prof Dr. Med. Heinrich Meng. Dozent für Psychohygiene an der Universität Basel. Zweite Reihe, Band I, "Bücher des Werdenden," begründet von Paul Federn und Heinrich Meng; herausgegeben von Heinrich Meng. Second edition. Cloth. 24.80 Swiss francs. Pp. 227. Hans Huber, Marktgasse 9, Bern 16 [Sole distributors for U. S. A. and Canada, Grune & Stratton, Inc., Publishers, 381 Fourth Ave., New York 16], 1953.

The author presents a comprehensive discussion of the question to what extent coercion and punishment are needed to supplement instruction and example in the rearing of youth. The opening chapters on the history of penology and pedagogy reveal the frightening significance of this problem today; it must be solved if the threat of human self-extermination is to be averted. The excellent closing section of 82 pages is a compact collection of quotations from both classic and recent source material. It is followed by author and subject indexes. This thoughtful, humane book deserves to be translated into English.

Copying and Duplicating Medical Subjects and Radiographs. By H. L Gibson, Technical Editor, Eastman Kodak Company, Rochester, N York. Publication number 136, American Lecture Series, monograph American Lectures in Medical Photography. Edited by Ralph P. Cr F.R.P.S., F.B.P.A., Secretary, Committee on Medical Motion Pictu American Medical Association. Cloth. $5. Pp. 75, with illustrati Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfi Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxf England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

Beginning with a brief outline of the basic techniques volved in photographic copying and duplicating, Gibson t proceeds to cover, in a well-organized manner, the spec techniques of copying black and white as well as colo originals, duplicating colored transparencies in black white, duplicating negatives and lantern slides, and re ducing radiographs. In each instance the types of equip needed, including camera, lighting, and film, are conside The material is presented so that it will be of value to relative beginner in medical photography and will also s as a review for the more advanced worker. The chapter copying black and white and colored originals and material on duplicating radiographs are especially well sented and will be helpful to the physician who is intere in clinical photography. The book is well documented, many illustrations of superior quality.

Rehabilitation of the Physically Handicapped. By Henry H. Ke Second edition. Cloth. $4. Pp. 275. Columbia University Press, Broadway, New York 27; Oxford University Press, Amen House, War Sq., London, E.C.4, 1953.

This book is a revision of the original text by Dr. Kes who has had over 30 years' experience in rehabilitating physically handicapped. The first part of the book consi the problems of the crippled child, the injured worker, disabled veteran, the chronically disabled. The second po deals with the basic principles of rehabilitation in term physical restoration, rehabilitation centers, vocational guid vocational training, and job placement. The third se deals with rehabilitation problems encountered in the men and emotionally disabled, the orthopedic patient, the patient, and medical and surgical invalids. A final sectio the book contains an interesting discussion of legislation administration in relation to a national program of reh tation. The text provides very interesting reading, tellin general without great detail regarding specific techniques procedures have been effective in accomplishing the reh tation of the handicapped. It is further enhanced by the pr tation of numerous case reports. This book will be of ticular interest to all those working in the broad fiel rehabilitation and to the handicapped themselves.

Operative Surgery, Volumes I and II. By Guy W. Horsley, B.S., F.A.C.S., Associate Professor of Surgery, Medical College of Vi Richmond, and Isaac A. Bigger, M.D., F.A.C.S., Professor of Su Medical College of Virginia. Sixth edition. Cloth. $30 per set 714; 715-1579, with 1274 illustrations by Helen Lorraine. C. V. Mosb 3207 Washington Blvd., St. Louis 3, 1953.

The first edition of this book was published in 1921 the fifth in 1940. The senior author, Dr. J. Shelton Ho died shortly after World War II ended, and it was decid cease publication of this distinguished text for a time. a happy circumstance that this decision was reversed. present work is dedicated to the author of the original and represents the combined efforts of 20 members o faculty of the Medical College of Virginia. It is, in re a new text, for the older work has been complete written and brought up-to-date. There are 45 chapte volume 1 and 42 in volume 2. Most of the sections are written and adequately illustrated. The text is easy to re

Drs. Horsley and Bigger have stated frankly in the pr their concept of the general surgeon: "The authors b that there is danger in too high a degree of specializ and also believe it is necessary that surgeons be br trained, even though they may later restrict their wor certain areas or systems within the body." When Dr. Ho published the first edition, he called attention to the impor of considering the physiological problems of the sur patient. In some sections in this new edition, the physiological approach to the surgical problems described is not discussed as adequately as it could have been. An example of this is found in the chapter on the liver, gallbladder, and bile tract. The bibliographies found at the end of each chapter often are not as complete or as discriminating as they should be. In spite of these criticisms, however, there is still to be found in these two volumes a wealth of material clearly presented and easily read. They will be helpful for reviewing specific techniques in a broad field of operative surgery.

Clinical Tropical Diseases. By A. R. D. Adams and B. G. Maegraith. Cloth. $10.50; £2. Pp. 508, with 65 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book was written to "supply essential facts as dogmatically and concisely" as possible. In an attempt to achieve the first objective, all references to original sources have been eliminated. To serve the second objective, details commonly found in textbooks of parasitology and bacteriology have been reduced to a minimum, since the principal aim was to provide useful clinical information on diseases occurring commonly in the tropics. The first innovation that meets the eye is the order of presentation, namely, by alphabetic arrangement of subjects, beginning with "ainhum" and ending with "yellow fever." In most cases it is easy to follow the sequence by referring to the table of contents or to the subject headings at the top of each right-hand page. It is difficult, however, to understand why dermatomycoses and scabies are associated, even from a strictly clinical viewpoint, and why nutritional disorders are considered in one chapter and the sprue syndrome separately nearly 100 pages later.

As the reader might expect from the distinguished authors of this volume, the facts are, for the most part, authoritatively and clearly presented. In some instances, however, information concerning the geographical distribution of a disease is inaccurate and misleading, as, for example, the statement that vesical schistosomiasis is "established . . . in Asia Minor," without including foci of high endemicity of this disease in Arabia, Iraq, northern Syria, and Iran (page 317). Possibly the designation "Asia Minor" has a different connotation among British and American geographers. Similarly, Manson's schistosomiasis is incorrectly stated to be indigenous to Central America, but there is no mention of its endemicity in several parts of the West Indies (page 323). Moreover, there is no evidence that dracontiasis exists today in the Caribbean Islands and northern South America (page 73). The most valuable topic in each chapter is the description of the disease as a clinical entity. However, since laboratory methods must usually be employed to confirm the presumptive diagnosis and since clinical laboratory procedures are frequently not sufficiently detailed in the present volume, the reader would need to consult texts on parasitology, bacteriology, and hematology for essential techniques and evaluation of the findings. Advice on treatment generally is sound and timely. In diseases such as amebiasis and malaria, a preference is expressed for drugs that are readily available in British Commonwealth countries, not necessarily those employed currently by American physicians. It is astonishing to find that acetarsol (acetarsone N.F.), which is poorly tolerated, is recommended in combined antiamebic therapy instead of other arsonic acid derivatives (page 13); that mepacrine methanesulfonate B. P. (quinacrine hydrochloride U.S.P.) is listed in preference to chloroquine in the treatment of malaria (page 221); and that pamaquine naphthoate rather than primaquine is advised for use in combination with quinine or chlorguanide hydrochloride for relapsing vivax infections (page 222).

A number of the cosmopolitan diseases are treated extensively, including bacilliary dysentery, brucellosis, rabies, smallpox, and typhoid, since all of these are today more important in tropical than in temperate climates. Yet no mention is made of tuberculosis, which is one of the really serious diseases of native populations in the tropics, or of poliomyelitis, which is becoming established in Central Africa and other warm areas. The authors may have had justifiable excuse for these omissions, but no explanation has been offered. The appropriateness of the title "Clinical Tropical Diseases" could be questioned. Should it not have been "Diseases of Warm Climates" or "Clinical Aspects of Diseases in the Tropics"? In conformity with the purpose of the volume the latter would seem to be more descriptive of the contents. Several typographic errors have been noted, mostly of a technical nature. Among these is "pruritus," which is consistently misspelled "pruritis."

The textual material of some chapters is supplemented with well-selected clinical photographs and charts, a few good photomicrographs and half-tone illustrations, and a few relatively poor line drawings of the diagnostic stages of etiological agents. There is a fairly extensive subject index, which, however, fails to include many of the common names of the diseases considered and several of the drugs recommended. There is no bibliography. Since no sources are mentioned in the text, no author index is provided. The volume is pleasingly printed and is bound in insect-proof cloth. Many of the shortcomings of this text are common to first editions, and the more obvious ones undoubtedly will be corrected in a second edition. For the most part they are outweighed by the valuable clinical information that has been provided. By and large the authors have achieved their purpose. This book should prove to be a useful and ready reference to students and practitioners of medicine in warm climates.

New and Nonofficial Remedies: Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1953. Issued under direction and supervision of Council on Pharmacy and Chemistry, American Medical Association. Cloth. $2.65. Pp. 623. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

The present edition of "New and Nonofficial Remedies" strikes one immediately as being smaller than preceding volumes. This is due mainly to the fact that the section on tests and standards for accepted nonofficial preparations is now published in a separate volume. Since interest in the book was felt to be largely either medical or pharmaceutical, the new arrangement should be more appealing to most users of the book. Examination of the 23 chapters into which descriptions of accepted preparations are divided reveals no remarkable or extensive revisions except for the addition of some 35 new monographs and the replacement of the monograph "Synthetic Oleovitamin D" (because of the omission of viosterol in oil) by appropriate expansion of the monograph on calciferol-U.S.P. Viosterol in oil was omitted under the Council's policy for exemption of articles that have been retained in the U.S.P., N.F., or N.N.R. for at least 20 years. Exempted preparations are listed in the index with reference to the last edition in which they appeared; some 25 such references to the 1952 volume appear in the present index.

Several of the new monographs, which detail the definition, actions, uses, and dosages of newly accepted agents, are worthy of special mention, together with the corresponding brands accepted prior to Jan. 1, 1953: carbacrylamine resins (Carbo-Resin—Lilly), a mixture of carbacrylic resin, potassium carbacrylic resin, and polyamine-methylene resin for oral use as an adjunct to increase the fecal excretion of sodium in the treatment of edema; chlorotrianisene (TACE—Merrell), a nonsteroid estrogen; hexamethonium chloride (Methium chloride—Warner-Chilcott), a ganglionic blocking agent for use as a hypotensive agent; alkavervir (Veriloid—Riker), an extract of Veratrum viride for the same purpose; methantheline bromide (Banthine bromide—Searle), a parasympatholytic agent having anticholinergic as well as ganglionic blocking action; probenecid (Benemid—Sharp & Dohme), used as a urate eliminant in gout and as an adjunct in intensive penicillin or *p*-aminosalicylic acid therapy to increase blood levels of these anti-infectives; polymyxin B sulfate (Aerosporin sulfate—Burroughs Wellcome), a new antibiotic for intramuscular, intrathecal, or topical administration; streptokinase-streptodornase (Varidase—Lederle), a mixture of proteolytic enzymes derived from a strain of Streptococcus hemolyticus; and isoniazid (Nydrazid—Squibb, Pyrizidin—Nepera, Tyvid—Merrell), an isonicotinic acid derivative highly active against tuberculosis. The editing, indexing, printing, and binding of this book are up to the publisher's usual standard of excellence.

QUERIES AND MINOR NOTES

DISPLACED INTERVERTEBRAL DISK

To the Editor:—*The roentgenograms of one of my patients showed a narrowing of the space between the third and fourth lumbar vertebrae with osteoarthritis of the lumbar spine. A later myelogram indicated a displaced disk between these vertebrae. The patient complains of pain, especially in the right leg, thigh, and lower back, and obtains relief only by lying in bed. Sitting or standing causes the pain to return. He also has severe pain when sneezing or coughing. Would surgical removal of this disk benefit my patient, and might there be some crippling after-effects? Should the treatment be undertaken by a neurosurgeon or an orthopedist?*

John H. Brothers, M.D., Providence, R. I.

Answer.—Protruded intervertebral disks are managed differently in different sections of the country. In some sections the operation on the disk is performed by a neurosurgeon and in other sections by an orthopedist. In some places patients with protruded disks are seen by both an orthopedist and a neurosurgeon, and, working together, they decide on the treatment. If treatment is simply the removal of a protruded disk, a neurosurgeon performs it, but if, in addition, it is believed that a spinal fusion should be performed, this is done by the orthopedist. The decision whether to perform a fusion is difficult and usually depends on the presence of static pain in the back if the patient is relatively young and whether immobilization of a portion of the spinal column is considered necessary for relief.

Statistics vary as to the results obtained from operations on disks, and in a large series of cases satisfactory results were reported in about 61% following removal of the disk alone. A slightly better result was obtained in the patients in whom spinal fusion was also performed. In this patient the displaced disk is between the third and fourth lumbar vertebrae, but if the osteoarthritic changes occur throughout the entire lumbar portion of the spinal column, it would be questionable whether fusion would be advisable. If the arthritic changes were localized to the one joint only, fusion might be beneficial. The decision to perform spinal fusion would depend on the age of the patient. If the nerve roots are not already damaged, crippling after-effects usually do not result from a disk operation.

AMOUNT OF ALCOHOL THAT CAN BE TOLERATED

To the Editor:—*How many ounces of whisky (86 proof) can a normal healthy adult consume as a daily ration? How many ounces of beer can be taken as a daily ration? How many ounces of wine can be taken as a daily ration without impairing health? Does mixing these alcoholic beverages have any adverse effect?*

M.D., New York.

Answer.—For the questions about the amount of alcohol that can be tolerated to be answered, it must be understood that the effect of alcohol depends largely on one factor, namely, the amount of alcohol that accumulates in the blood. The amount accumulated depends on the amount ingested, the size of the person, the concentration of alcohol in the beverage, the presence of food in the stomach, the rate of oxidation and elimination of the alcohol, and, particularly, on the rate of drinking. The average person can oxidize and eliminate about 6 to 10 cc. of pure alcohol per hour, so that he could consume about a pint (500 cc.) of 100 proof whisky in 24 hours without ever being intoxicated if he spaced his drinks properly. This experiment would, of course, have academic value only, since the consumption of alcohol below the rate of accumulation involves no satisfaction to the drinker. On the other hand, a single drink consumed rapidly on an empty stomach may produce measurable symptoms of intoxication. The relative intoxicating effects of whisky, beer, and wine depend chiefly on the amount of alcohol consumed but also on the dilution, so that the same amount of alcohol taken in various drinks will have the least effect when taken as beer and the greatest effect when taken as straight whisky. A convenient guide for comparison of the amount of alcohol in beverages is that 1 oz. (30 cc.) of 100 proof whisky contains about as much alcohol as 3 oz. (90 cc.) of wine (17% by volume) or 12 oz. (360 cc.) of beer (4% by volume, 3.2% by weight). The general health of a person is probably not affected by the use of alcohol as long as the alcohol is not used as a substitute for food and vitamins. Aside from the irritating action of strong alcohol on the gastric mucosa, other tissues such as the circulatory system, kidneys, and liver are probably not permanently affected by the small concentration of alcohol that can accumulate in the body. This concentration in body fluids reaches only about 0.7% in cases of death due to alcohol. The possibility of addiction to alcohol must always be considered, however, and the physician who advises patients to use beverage alcohol may be criticized if addiction occurs. The greatest danger from the use of these beverages concerns the relationship of drinking to activities. For example, the after-dinner drinks may be perfectly harmless if no important activities are undertaken at such times, whereas the drink taken before driving a car, running machinery, or performing any task that demands accurate decisions or mental acuity might be dangerous. The drinker should observe the following rule: For every two drinks he should wait three hours before undertaking important activities. Contrary to popular opinion, the mixing of alcoholic drinks does not increase the intoxicating effects of alcohol, since these symptoms depend on the actual amount of alcohol consumed and the other factors mentioned. However, this old wives' tale concerning the mixing of beverages may be of value, since promiscuous sampling may lead to greater consumption of alcohol, just as a great variety of foods may lead to overeating

CEMENT AND RADIANT-HEATED FLOORS

To the Editor:—*Is a cement floor on the ground without basement underneath conducive to rheumatoid conditions Does a floor with radiant heat cause excessive sweatin of the feet?*

M.D., Lake Mills, Wis.

Answer.—The causes of rheumatoid conditions are bacterial, endocrine, neurogenic, and possibly emotional. Dampness and cold involving high humidity will not, per se, produc such conditions. The question then becomes whether a col damp climate will unfavorably influence a rheumatoid stat Many persons with joint or bone conditions predict, althoug oftentimes erroneously, the coming of inclement weather, an many such persons fare better living in climates such as that c Arizona or Florida. The reason for this is partly the subjectiv and emotional state brought on by the mental depressio accompanying inclement weather. However, in part the condition results from impaired heat regulation, defective ski elimination, and distorted metabolism. While a dark, damp cold basement apartment is undesirable for all human being the same condition could be brought about on the 10th floo The only reason that a bare cement floor attracts attentio is the chilling and discomfort that derives from the rapid los of heat from contact with the cement floor. A steel floo would be much worse, and correspondingly a wooden floo would be better than either. A specific answer to this comple question is "yes."

The situation with regard to radiant floor heating is muc different. The floor area emitting heat is so large that unde proper conditions the floor temperature is only slightly highe

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

than the room temperature. The inhabitant of such a heated space ordinarily is not aware of the heat source in the floor except possibly in the local areas where the warmer air or water first enters the floor space prior to dispersion. Unless there is overheating, the temperature of the soles of the feet always is higher than that of the surface of the floor, so that the thermal exchange would favor the floor and not the feet. This would result in foot cooling rather than foot overheating, and would not cause unusual sweating of the feet.

POLYCYTHEMIA VERA

To the Editor:—*A patient has polycythemia vera. A normal hemogram follows administration of radioactive phosphorus (P^{32}), but the patient still has severe paresthesias. I would like to know the cause and the treatment; whether such a patient should avoid high altitudes; how early in this disease marrow changes take place; and whether cardiac arrhythmias occur early and if of any prognostic significance?*

M.D., Illinois.

Answer.—In polycythemia vera, paresthesias may be due to dilatation of the vessels of the skin, which persists to some extent even when the blood cell count is normal. There is no satisfactory treatment for this condition. In some patients the condition is aggravated by a hot bath and in others cold weather has an adverse effect. Such persons should, of course, attempt to protect themselves from the temperature that makes them uncomfortable. Small doses of irradiation given locally sometimes may be of benefit.

Regarding high altitudes, patients with polycythemia tend to bleed easily from mucous membranes, but if the blood cell count is normal as described above, the patient would probably not suffer from a change of altitude. If he is going to a very high place for a long time, some erythrocytosis due to high altitude might be superimposed on the recurring polycythemia vera. If one can diagnose the disease clinically and by peripheral blood studies, then marrow changes such as increase in cellularity, including all the elements, especially the megakaryocytes, probably have already occurred. Cardiac arrhythmias are not more frequent in polycythemia vera patients than in other persons of the same age group.

LEUKEMIA

To the Editor:—*A 24-year-old man has chronic myelocytic leukemia that was diagnosed two years ago. His only treatment to date has been a course of x-ray irradiation to his spleen of 400 r three months ago. His spleen shrank markedly but has since enlarged greatly again. He has been admitted to a hospital because of fever of about 10 days' duration, with daily elevations of 103 to 105 F. No cause has been found for this aside from leukemia. His spleen extends several inches below the umbilicus and several inches to the right of the midline. He also has anorexia, weight loss, fullness before his meals are finished, nausea, and vomiting. No lymph nodes are enlarged. His hemoglobin level, which was 6.6 gm. per 100 cc., has been brought up to 10 gm. by transfusions. On admission his white blood cell count was 60,000. Several days later it was 30,000, and about a week later it was down to 15,000. The differential count shows 45 neutrophils, 9 lymphocytes, 20 band forms, 6 myelocytes, 10 juvenile forms, 10 premyelocytes, and 0 myeloblasts. The platelet count is 60,000. No hemorrhage has been noted. What is the best plan of therapy?*

M.D., Pennsylvania.

Answer.—The occurrence of fever with daily elevations to 103 and 105 F in a patient with chronic myelocytic leukemia compels the assumption of either a conversion to acute leukemia or the presence of a serious complicating disease. The dropping white blood cell count, the low platelet count, and the large numbers of premyelocytes suggests that this is a conversion to acute leukemia. This can best be established by the examination of the patient's marrow, which may show changes not yet recognizable in the peripheral blood. The possibility of a complicating infection, especially miliary tuberculosis, must, however, be considered, since tuberculosis occurs frequently as a complication of leukemia and could account for the rapid enlargement of the spleen, the "hypersplenism" (pancytopenia), and the fever. The weight loss, anorexia, and other gastrointestinal symptoms may well have a mechanical basis secondary to pressure of the spleen on the stomach. Before therapeutic recommendations can be made, a precise diagnosis will have to be established. X-ray examination of the chest and examination of the marrow and sputum should help. If miliary tuberculosis is present, therapy should be directed towards its control. On the other hand, if this represents a conversion of chronic leukemia into acute leukemia, only transfusions of blood and antibiotics will be indicated. The recently introduced 6-mercaptopurine offers some possibility of lessening the severity of the exacerbation.

HERPES ZOSTER

To the Editor:—*A woman, aged 75, has been suffering from herpes zoster for seven weeks. I have used 16 ampuls of Protamide (a colloidal solution of a proteolytic enzyme), large injections of vitamin B_1, x-ray therapy, crystalline vitamin B_{12} (Be-Dodec), and finally a cobra venom derivative (Cobroxin). The lesions were covered with diphenhydramine in a calamine base (Caladryl). Nothing has relieved the pain to any extent. She was seen by an excellent neurologist, who suggested that I try the cobra venom derivative and who did not feel that surgical procedures would be very helpful.*

Ernest W. Dales, M.D., Grand Rapids, Mich.

Answer:—There is no specific therapy for herpes zoster, and the measures employed are merely symptomatic. Although most patients recover without any residual symptoms, postherpetic neuralgia may persist for months or even years. In this case, the use of snake venom as suggested by the neurologist is infrequently of value. Analgesics are usually unsuccessful. In some instances, a nerve block with procaine or one of its derivatives may bring relief to the hyperesthetic area. In the occasional case, deep x-ray therapy may also afford some relief. Surgical procedures such as sectioning of the sensory root of the ganglion or of the affected posterior roots (in cases of spinal cord involvement) are also effective in some instances. Within the past year, the use of cortisone or corticotropin (ACTH) (and the preference seems to be for the latter) has also been of value in certain instances. In view of this patient's age, these drugs should be administered with extreme caution and with close supervision, with particular reference to side-effects. The antibiotics are occasionally of value in the acute stage but would be ineffectual in this case.

BURN OF HAND

To the Editor:—*On Sept. 18, 1951, a patient was using an acetylene blowtorch to cut a piece of iron. The "slag" dropped into the palm of the right hand, causing a burn that will not completely heal. There is a group of vesicles the size of a dollar, some of which contain pus. Cultures of the contents of vesicles have been negative for fungi. The patient has had 8 or 10 x-ray treatments, with no appreciable result. I have been treating this man's hand with a desquamating ointment of 20% salicylic acid and nitrofurfuryl methyl ether (Furaspor) cream used alternately at bedtime, since May 18, 1953. Have you any advice on this subject?*

M.D., Washington.

Answer.—A burn due to the events described should eventuate in healing of the lesion within a few weeks or, at most, a few months. If the lesion has failed to heal after two years, a more thorough investigation is in order. The contents of the vesicles should be rechecked in the laboratory for bacteria and fungi. Furthermore, a biopsy specimen should be examined to rule out the possibility of malignancy. During this period, therapy should consist solely of application of a bland emollient such as ordinary petrolatum, in conjunction with a mil astringent wet dressing (such as aluminum acetate [Bur

QUERIES AND MINOR NOTES

DISPLACED INTERVERTEBRAL DISK

To the Editor:—*The roentgenograms of one of my patients showed a narrowing of the space between the third and fourth lumbar vertebrae with osteoarthritis of the lumbar spine. A later myelogram indicated a displaced disk between these vertebrae. The patient complains of pain, especially in the right leg, thigh, and lower back, and obtains relief only by lying in bed. Sitting or standing causes the pain to return. He also has severe pain when sneezing or coughing. Would surgical removal of this disk benefit my patient, and might there be some crippling after-effects? Should the treatment be undertaken by a neurosurgeon or an orthopedist?*

John H. Brothers, M.D., Providence, R. I.

Answer.—Protruded intervertebral disks are managed differently in different sections of the country. In some sections the operation on the disk is performed by a neurosurgeon and in other sections by an orthopedist. In some places patients with protruded disks are seen by both an orthopedist and a neurosurgeon, and, working together, they decide on the treatment. If treatment is simply the removal of a protruded disk, a neurosurgeon performs it, but if, in addition, it is believed that a spinal fusion should be performed, this is done by the orthopedist. The decision whether to perform a fusion is difficult and usually depends on the presence of static pain in the back if the patient is relatively young and whether immobilization of a portion of the spinal column is considered necessary for relief.

Statistics vary as to the results obtained from operations on disks, and in a large series of cases satisfactory results were reported in about 61% following removal of the disk alone. A slightly better result was obtained in the patients in whom spinal fusion was also performed. In this patient the displaced disk is between the third and fourth lumbar vertebrae, but if the osteoarthritic changes occur throughout the entire lumbar portion of the spinal column, it would be questionable whether fusion would be advisable. If the arthritic changes were localized to the one joint only, fusion might be beneficial. The decision to perform spinal fusion would depend on the age of the patient. If the nerve roots are not already damaged, crippling after-effects usually do not result from a disk operation.

AMOUNT OF ALCOHOL THAT CAN BE TOLERATED

To the Editor:—*How many ounces of whisky (86 proof) can a normal healthy adult consume as a daily ration? How many ounces of beer can be taken as a daily ration? How many ounces of wine can be taken as a daily ration without impairing health? Does mixing these alcoholic beverages have any adverse effect?*

M.D., New York.

Answer.—For the questions about the amount of alcohol that can be tolerated to be answered, it must be understood that the effect of alcohol depends largely on one factor, namely, the amount of alcohol that accumulates in the blood. The amount accumulated depends on the amount ingested, the size of the person, the concentration of alcohol in the beverage, the presence of food in the stomach, the rate of oxidation and elimination of the alcohol, and, particularly, on the rate of drinking. The average person can oxidize and eliminate about 6 to 10 cc. of pure alcohol per hour, so that he could consume about a pint (500 cc.) of 100 proof whisky in 24 hours without ever being intoxicated if he spaced his drinks properly. This experiment would, of course, have academic value only, since the consumption of alcohol below the rate of accumulation involves no satisfaction to the drinker. the other hand, a single drink consumed rapidly on an en stomach may produce measurable symptoms of intoxicat The relative intoxicating effects of whisky, beer, and depend chiefly on the amount of alcohol consumed but on the dilution, so that the same amount of alcohol t in various drinks will have the least effect when taken beer and the greatest effect when taken as straight whi A convenient guide for comparison of the amount of alc in beverages is that 1 oz. (30 cc.) of 100 proof whisky tains about as much alcohol as 3 oz. (90 cc.) of wine (1 by volume) or 12 oz. (360 cc.) of beer (4% by volume, 3. by weight). The general health of a person is probably affected by the use of alcohol as long as the alcohol is used as a substitute for food and vitamins. Aside from irritating action of strong alcohol on the gastric mucosa, o tissues such as the circulatory system, kidneys, and liver probably not permanently affected by the small concentra of alcohol that can accumulate in the body. This concen tion in body fluids reaches only about 0.7% in cases of de due to alcohol. The possibility of addiction to alcohol m always be considered, however, and the physician who advi patients to use beverage alcohol may be criticized if addict occurs. The greatest danger from the use of these bevera concerns the relationship of drinking to activities. For ample, the after-dinner drinks may be perfectly harmless no important activities are undertaken at such times, wher the drink taken before driving a car, running machinery, performing any task that demands accurate decisions or men acuity might be dangerous. The drinker should observe following rule: For every two drinks he should wait th hours before undertaking important activities. Contrary popular opinion, the mixing of alcoholic drinks does not crease the intoxicating effects of alcohol, since these sympto depend on the actual amount of alcohol consumed and other factors mentioned. However, this old wives' tale c cerning the mixing of beverages may be of value, since p miscuous sampling may lead to greater consumption of al hol, just as a great variety of foods may lead to overeati

CEMENT AND RADIANT-HEATED FLOORS

To the Editor:—*Is a cement floor on the ground withou basement underneath conducive to rheumatoid conditio Does a floor with radiant heat cause excessive sweati of the feet?*

M.D., Lake Mills, Wis.

Answer.—The causes of rheumatoid conditions are b terial, endocrine, neurogenic, and possibly emotional. Dam ness and cold involving high humidity will not, per se, produ such conditions. The question then becomes whether a co damp climate will unfavorably influence a rheumatoid sta Many persons with joint or bone conditions predict, althou oftentimes erroneously, the coming of inclement weather, a many such persons fare better living in climates such as that Arizona or Florida. The reason for this is partly the subjecti and emotional state brought on by the mental depressi accompanying inclement weather. However, in part the co dition results from impaired heat regulation, defective sk elimination, and distorted metabolism. While a dark, dam cold basement apartment is undesirable for all human being the same condition could be brought about on the 10th floo The only reason that a bare cement floor attracts attentio is the chilling and discomfort that derives from the rapid los of heat from contact with the cement floor. A steel floo would be much worse, and correspondingly a wooden floo would be better than either. A specific answer to this comple question is "yes."

The situation with regard to radiant floor heating is much different. The floor area emitting heat is so large that under proper conditions the floor temperature is only slightly highe

POLYCYTHEMIA VERA

To the Editor:—*A patient has polycythemia vera. A normal hemogram follows administration of radioactive phosphorus (P^{32}), but the patient still has severe paresthesias. I would like to know the cause and the treatment; whether such a patient should avoid high altitudes; how early in this disease marrow changes take place; and whether cardiac arrhythmias occur early and if of any prognostic significance?*

M.D., Illinois.

Answer.—In polycythemia vera, paresthesias may be due to dilatation of the vessels of the skin, which persists to some extent even when the blood cell count is normal. There is no satisfactory treatment for this condition. In some patients the condition is aggravated by a hot bath and in others cold weather has an adverse effect. Such persons should, of course, attempt to protect themselves from the temperature that makes them uncomfortable. Small doses of irradiation given locally sometimes may be of benefit.

Regarding high altitudes, patients with polycythemia tend to bleed easily from mucous membranes, but if the blood cell count is normal as described above, the patient would probably not suffer from a change of altitude. If he is going to a very high place for a long time, some erythrocytosis due to high altitude might be superimposed on the recurring polycythemia vera. If one can diagnose the disease clinically and by peripheral blood studies, then marrow changes such as increase in cellularity, including all the elements, especially the megakaryocytes, probably have already occurred. Cardiac arrhythmias are not more frequent in polycythemia vera patients than in other persons of the same age group.

LEUKEMIA

To the Editor:—*A 24-year-old man has chronic myelocytic leukemia that was diagnosed two years ago. His only treatment to date has been a course of x-ray irradiation to his spleen of 400 r three months ago. His spleen shrank markedly but has since enlarged greatly again. He has been admitted to a hospital because of fever of about 10 days' duration, with daily elevations of 103 to 105 F. No cause has been found for this aside from leukemia. His spleen extends several inches below the umbilicus and several inches to the right of the midline. He also has anorexia, weight loss, fullness before his meals are finished, nausea, and vomiting. No lymph nodes are enlarged. His hemoglobin level, which was 6.6 gm. per 100 cc., has been brought up to 10 gm. by transfusions. On admission his white blood cell count was 60,000. Several days later it was 30,000, and about a week later it was down to 15,000. The differential count shows 45 neutrophils, 9 lymphocytes, 20 band forms, 6 myelocytes, 10 juvenile forms, 10 premyelocytes, and 0 myeloblasts. The platelet count is 60,000. No hemorrhage has been noted. What is the best plan of therapy?*

M.D., Pennsylvania.

Answer.—The occurrence of fever with daily elevations to 103 and 105 F in a patient with chronic myelocytic leukemia compels the assumption of either a conversion to acute leukemia or the presence of a serious complicating disease. The dropping white blood cell count, the low platelet count, and the large numbers of premyelocytes suggests that this is a conversion to acute leukemia. This can best be established by the examination of the patient's marrow, which may show changes not yet recognizable in the peripheral blood. The possibility of a complicating infection, especially miliary tuberculosis, must, however, be considered, since tuberculosis occurs frequently as a complication of leukemia and could account for the rapid enlargement of the spleen, the "hypersplenism" (pancytopenia), and the fever. The weight loss, anorexia, and other gastrointestinal symptoms may well have a mechanical basis secondary to pressure of the spleen on the stomach. Before therapeutic recommendations can be made, a precise diagnosis will have to be established. X-ray examination of the chest and examination of the marrow and sputum should help. If miliary tuberculosis is present, therapy should be directed towards its control. On the other hand, if this represents a conversion of chronic leukemia into acute leukemia, only transfusions of blood and antibiotics will be indicated. The recently introduced 6-mercaptopurine offers some possibility of lessening the severity of the exacerbation.

HERPES ZOSTER

To the Editor:—*A woman, aged 75, has been suffering from herpes zoster for seven weeks. I have used 16 ampuls of Protamide (a colloidal solution of a proteolytic enzyme), large injections of vitamin B_1, x-ray therapy, crystalline vitamin B_{12} (Be-Dodec), and finally a cobra venom derivative (Cobroxin). The lesions were covered with diphenhydramine in a calamine base (Caladryl). Nothing has relieved the pain to any extent. She was seen by an excellent neurologist, who suggested that I try the cobra venom derivative and who did not feel that surgical procedures would be very helpful.*

Ernest W. Dales, M.D., Grand Rapids, Mich.

Answer:—There is no specific therapy for herpes zoster, and the measures employed are merely symptomatic. Although most patients recover without any residual symptoms, postherpetic neuralgia may persist for months or even years. In this case, the use of snake venom as suggested by the neurologist is infrequently of value. Analgesics are usually unsuccessful. In some instances, a nerve block with procaine or one of its derivatives may bring relief to the hyperesthetic area. In the occasional case, deep x-ray therapy may also afford some relief. Surgical procedures such as sectioning of the sensory root of the ganglion or of the affected posterior roots (in cases of spinal cord involvement) are also effective in some instances. Within the past year, the use of cortisone or corticotropin (ACTH) (and the preference seems to be for the latter) has also been of value in certain instances. In view of this patient's age, these drugs should be administered with extreme caution and with close supervision, with particular reference to side-effects. The antibiotics are occasionally of value in the acute stage but would be ineffectual in this case.

BURN OF HAND

To the Editor:—*On Sept. 18, 1951, a patient was using an acetylene blowtorch to cut a piece of iron. The "slag" dropped into the palm of the right hand, causing a burn that will not completely heal. There is a group of vesicles the size of a dollar, some of which contain pus. Cultures of the contents of vesicles have been negative for fungi. The patient has had 8 or 10 x-ray treatments, with no appreciable result. I have been treating this man's hand with a desquamating ointment of 20% salicylic acid and nitrofurfuryl methyl ether (Furaspor) cream used alternately at bedtime, since May 18, 1953. Have you any advice on this subject?*

M.D., Washington.

Answer.—A burn due to the events described should eventuate in healing of the lesion within a few weeks or, at most, a few months. If the lesion has failed to heal after two years, a more thorough investigation is in order. The contents of the vesicles should be rechecked in the laboratory for bacteria and fungi. Furthermore, a biopsy specimen should be examined to rule out the possibility of malignancy. During this period, therapy should consist solely of application of a bland emollient such as ordinary petrolatum, in conjunction with a mildly astringent wet dressing (such as aluminum acetate [Burow' solution] in a dilution of 1 to 20), and should be continued for several weeks. Further measures would depend primarily on the findings encountered microscopically as well as by the clinical response to the preceding bland measures.

OPHTHALMIC OINTMENTS

TO THE EDITOR:—*I have read recently two articles condemning use of ophthalmic ointments in industry following corneal abrasions or the removal of imbedded foreign bodies. Before discarding this relatively common and time-honored procedure in a large industrial plant, we would appreciate some authoritative comment.*

M.D., California.

ANSWER.—Any ointment or antiseptic solution retards healing of corneal wounds and abrasions to some extent; however, the prevention of infection is so important that many authorities in industrial ophthalmology recommend them. Two authorities (E. P. Burch and G. H. Cross), writing in a standard textbook, recommend the use of an anesthetic and antiseptic ointment after the removal of a foreign body from the cornea and in severe abrasion of the cornea. Anesthetic solutions and ointments should be used sparingly, as both retard healing, and it is preferable to administer analgesics systemically to relieve pain. It has been routine practice with this consultant to instill an antiseptic ointment after the removal of a foreign body and for abrasions. This practice will be continued, although the use of local anesthetics will still be avoided so far as possible.

PAIN IN HEMIPLEGIC AREA

TO THE EDITOR:—*A 52-year-old white man has hemiplegia of the right side owing to cerebral hemorrhage. He is also aphasic. For a year and a half he has had almost continuous pain in the entire hemiplegic area. The pain bisects the body and is confined to his paralyzed side. I have used various narcotics but he had a shock reaction to 100 mg. of meperidine (Demerol), becoming colorless and pale with a weak to absent pulse and blood pressure of 60/40 mm. Hg. I have used methadone with fair results. What therapy will relieve his continuous pain?* *M.D., Pennsylvania.*

ANSWER.—The pain in this hemiplegic patient may have two possible sources; one is the muscular pain due to spasticity in the paralyzed side; the other is vascular or visceral pain that follows the pathway of blood vessels. All of the potent analgesics such as meperidine or opiates have a hypotensive factor that is characterized by a persistent histamine-like effect on the terminal blood vessels. Therefore, the hemiplegic patient is apt to have a greater drop in blood pressure than the normal person. By far the most effective therapy for the relief of this pain would be laminectomy and anterolateral cordotomy. This, however, must depend on the condition of the patient. Since the pain is of a visceral type, it should respond to procaine intravenously, which can be given as an infusion over a period of one hour in doses of 500 mg. If the procaine relieves the pain, the relief will be out of all proportion to the duration of the infusion; daily infusions may correct the painful condition. In the treatment of this patient with opiates or other habit-forming drugs, the possibility of addiction must be weighed against the risk of laminectomy.

PIGMENTED MOLES

TO THE EDITOR:—*I am aware of the danger of removing black moles by ordinary surgical methods. Please let me know whether this danger has been eliminated by the employment of an electrical cutting current.*

Heinrich F. Wolf, M.D., New York.

ANSWER.—Any method of removal of a black mole carries with it some element of risk, and the question as to whether one modality is better than another is still unsettled. There are no convincing statistics to settle the matter one way or the other. There is a strong feeling among some experienced observers that malignant moles are already malignant by the time the physician is consulted and that treatment has lit effect on their subsequent course. Shaw (*South. M. J.* 46: [March] 1953) found that most dermatologists on the ba of their experience favored electrosurgical methods. The pa presents an interesting and up-to-date discussion of the tre ment of pigmented moles.

BLACK DISCOLORATION BENEATH GOLD RING

TO THE EDITOR:—*In Queries and Minor Notes, Sept. 26, 19 page 455, is a reply to a Washington physician who wan information about black discoloration of the skin bene a gold ring. I wish to offer another explanation for phenomenon. The dermatologist is familiar with this m festation and refers to it as "black dermographism." complete description may be found in an article written Urbach and Pillsbury in* THE JOURNAL, *Feb. 13, 1943, p 485. Essentially, "black dermographism" is believed to a mechanical phenomenon in which a black line is produ by deposition of minute metallic particles on the skin. condition will take place when a powder of sufficient ha ness present on the skin is subjected to friction by cer metals. Face powder and street dust may fulfill the role in this patient's complaint, while less than 18 c gold (which contains a sufficiently high copper content render adequate hardness) fulfills the second requirement the phenomenon. The color of the powder present on skin has no effect on the result.*

TRICHLORETHYLENE (TRILENE) ANESTHESIA

TO THE EDITOR:—*In the answer to the question on trichl ethylene (Trilene) anesthesia in Queries and Minor No Oct. 17, 1953, there is one point that seems to dese comment. In his authoritative monograph, "Trichlorethyl Anesthesia" (Edinburgh and London, E. & S. Livingst Ltd., 1953) Dr. Gordon Ostlere points out that the portant toxic product produced when trichlorethylene passed through soda lime is dichloracetylene and that production of phosgene in significant quantities is unlik under the conditions of administration. Dichloracetyl may produce, even in minute quantities, trigeminal pa which is the most feared complication of this anesth agent. In addition, it seems possible that use of a clo soda lime absorption system after previous administrat of trichlorethylene may be hazardous inasmuch as eli nation of the drug is slow. Ostlere reports a case trigeminal palsy developing under such circumstances. T additional information would seem important inasmuch the use of trichlorethylene is becoming more widespre Careless administration may result in the above compli tion with subsequent unjust criticism of the drug.*

Hamilton S. Davis, M.D.
Western Reserve Universit
2065 Adelbert Rd.
Cleveland 6.

TO THE EDITOR:—*In* THE JOURNAL, *Oct. 17, 1953, page 6 in answer to a query regarding how soon a different an thetic may be used through the soda lime tower af trichlorethylene has been used, it is simply stated that short interval should be allowed to elapse. The followi case in Gordon Ostlere's book "Trichlorethylene Anesthesi shows how easily cranial nerve palsy may be produced the decomposition products of trichlorethylene over so lime. "A woman in labor had self-administered trichl ethylene analgesia in her home, under the supervision of midwife. She was then brought to the hospital, whe Caesarean section was performed under cyclopropane ane thesia. She developed a trigeminal palsy, and when t anesthetist later investigated the closed-circuit apparatus breathing from it he developed a similar lesion himself*

ROENTGEN EXAMINATION OF THE COLON

CHAIRMAN'S ADDRESS

Paul C. Hodges, M.D., Chicago

The x-ray examination of the colon dates back to the previous century and to the earliest days of radiology, but it did not become a major clinical tool until the enema with opaque material displaced the oral administration of bismuth in 1911.[1] Barium sulfate supplanted bismuth salts a few years later. In this examination, as in so many others, the competence and diligence of the examiner are vastly more important than the precise nature of the techniques he employs, and a simple mixture of barium and water poured through a glass funnel under the supervision of a Harry Weber[2] is superior to a homogenized gum suspension introduced through a four-way valve by a novice, particularly if that novice is bored and overworked. But, while it is true that a master craftsman using the simplest tools can do superlative work, it is true also that even the expert's output can be increased by better tools, to say nothing of the output of the less skilled worker. When the work in question is the x-ray examination of the colon, it is important indeed that output be increased. At my own institution, for example, the daily scheduling of 20 colon examinations barely meets the current needs of our clinical colleagues, and if we were to proceed at the leisurely pace suggested by some teachers, these 20 examinations would tie up a team and a room for a full day instead of the half day we now devote to it.

Medium and large neoplasms, diverticulosis, diverticulitis, and ulcerative colitis can be diagnosed rapidly and dependably by reasonably experienced, reasonably diligent radiologists, almost without regard to the particular technique they employ, and surgeons and internists quite properly place great dependence on the radiologist's reports of his fluoroscopic and film findings in those conditions. If we were able to do nothing more than diagnose gross lesions, our barium enema examinations would continue to be major contributions to the understanding of colon disease, but it is generally agreed that further improvement in the cure rate of colon neoplasm requires that in addition we become able to detect small polyps while they are still benign.[3] The proctoscopist should be responsible for diagnosing those polyps that lie within the reach of his instrument, but above that level only radiology will suffice, and even it will succeed only when special techniques are employed. These techniques have to do with all three phases of the examination: first, the preparation of the patient; second, the nature and concentration of the vehicle in which the barium is suspended; and third, the amount of enema administered, the manner of its introduction and removal, and the manipulation of the patient during fluoroscopy and filming.

PREPARATION OF THE PATIENT

Ideally the barium enema should be administered only after the colon has been rendered completely free of feces, fluid, and gas, but we are ignoring our education and experience as physicians if we assume or even hope that the ideal can ever be accomplished. Few situations in medicine have called forth quite so much spoken and written foolishness as this one. Few orders to patients and nurses involve quite so much inconvenience and wasted effort as the fatuous order: "Repeat saline enemas until the return is clear." I do not pretend to know the perfect means of preparing the patient for the x-ray examination of the colon, but I am convinced that cleansing enemas are a poor means and that they should be avoided whenever possible. As usually administered by the patient, an orderly, or a nurse, such enemas introduce a considerable amount of air along with the salt solution, and the fluid

and air usually are incompletely expelled. If the enemas are given at home, the subsequent trip to the radiologist is hazardous, particularly if it has to be made by public transportation in a large city, and, if they are given in the x-ray department, a heavy additional load is placed on waiting space, dressing rooms, and technical staff. If the patient is in the hospital and the examination is scheduled for a morning hour, the task of administering a series of early morning enemas constitutes an almost unbearable added burden for short-handed, desperately overworked nursing staffs. Most important of all, it is our experience that these repeated cleansing enemas, which are so costly in time and effort, are less effective than the simpler alternative of administering 2 ounces (60 cc.) of castor oil on the day preceding the examination. Formerly we administered the oil at bedtime and allowed the patient to take supper, but there is reason to believe that a change recently made in this program will provide better preparation. The patient takes only clear liquids for 24 hours before the colon examination and then takes 2 ounces of castor oil 20 hours before the examination. Our orders to the patient stipulate exactly what is meant by clear fluids. He is allowed to take at will water, coffee, or tea with sugar, carbonated beverages, sweetened fruit juices, and clear soups. He is denied cream soups, gravies, noodles, crackers, milk, cream, eggs, and all solid foods. Such a regimen allows an outpatient to continue light work until the onset of catharsis and makes it possible for the inpatient to undergo other examinations and tests up to the hour of his x-ray appointment. It cannot be expected to succeed in all cases, but neither do saline enemas always succeed, regardless of how skillfully they are administered or how frequently they are repeated.

It has been argued that 1 ounce (30 cc.) of castor oil is as effective as 2 ounces, the second ounce merely remaining in the alimentary tract as droplets, which may simulate small polyps.[4] We have not experienced such difficulties, but we do know that the prescribing of 2 ounces of castor oil increases the likelihood that the patient will ingest at least 1 ounce in spite of the large residue that he almost invariably leaves in the bottle from which he pours the oil and the glass from which he drinks it. Because patients have such an aversion to castor oil, we, like others, have tried substituting less disliked cathartics but have found none that was equally effective. After all, the barium enema itself is not pleasant for the patient, and if it is worth while to subject him to that ordeal it should be worth while to insist that he take the cathartic most likely to render the examination effective.

FORMULATION OF THE BARIUM ENEMA

Insoluble barium sulfate has been the standard opaque medium for the alimentary tract for more than 30 years, and modern barium sulfate U. S. P. for x-ray diagnosis is plentiful, cheap, and conforms to rigid standards of purity. Much of the annual output of this highly purified barium sulfate is sold directly to radiologists or hospital pharmacies, where it is dispensed as a suspension in water alone or, more frequently, in water that has been thickened by kaolin,[1] starch,[5] agar, gelatine or one of the natural or synthetic gums.[6] Another large portion of the product is processed for or by drug houses, manufacturers of x-ray apparatus, or dealers, to be marketed by them under brand names.[7] Such processing consists in the addition of powdered acacia, tragacanth, pectin, gelatine, starch, methylcellulose, or some other suspending agent, plus sugar or saccharin and one or more flavoring agents. Some of the mixtures contain a little sodium carbonate and tartaric acid to produce effervescence. Some include aluminum silicate,[8] aluminum hydroxide, malted milk, or lecithin. In at least one instance the dry ingredients are mixed with water, run through a colloid mill, and sold to the consumer ready for use without further dilution. Unfortunately, only a few of these proprietary mixtures carry labels that are really informative, and in many instances the labels appear to have been composed by sales managers rather than chemists or pharmacists and seem calculated to mislead rather than to inform. Some such labels describe a "colloidally stabilized barium"; some speak of a "micro barium" and imply or even state that special processing has reduced the grain size of the barium sulfate, with resulting great improvement in its ability to adhere to intestinal mucosa. In some instances it is alleged that the pH of the barium particles has been "adjusted to the pH of the intestinal mucosa," with the result that the barium will flock out of suspension when it comes in contact with the mucosa.

There has been speculation and some experimental work concerning the possible clinical advantage of using barium sulfates in which the grain size is extremely small. A manufacturing chemist presently will make available to us barium sulfate having a grain size only one-tenth as large as that of his standard product. He believes it will have no advantage over ordinary barium, and, though we are inclined to agree with him, we will defer judgment until we have conducted clinical tests.

DEFINITION OF TERMS

Colloid chemistry is a field to itself, one in which even good physical chemists tread lightly, in which a nonchemist like myself proceeds at his own risk, and in which a little learning truly is a dangerous thing. I am told that modern colloid chemists use the term "colloidal" rather freely without too much reference to the size of the particles being suspended and without sharp distinction between the situation in which the particles are suspended by virtue of their own size and degree of hydration and the other situation in which larger particles are held in suspension because the dispersion medium has been thickened by the addition of emulsion colloids such as starch or gums.

[8] Comparative Study of Clinical Bismuth Treatments, report of the Council on Pharmacy and Chemistry, J. A. M. A. **102**: 930 (March 24) 1934.

When colloid chemists are speaking to one another there is little risk of confusion if the term "colloidal barium sulfate" is applied to suspensions in gum of the sort we have all used for more than three decades, but such terminology is confusing to outsiders. Most physicians think of colloidal gold as a typical example of the colloid state and unless warned against it are apt to assume that the term "colloidal barium sulfate" connotes a material with a grain size ranging from 0.1 to 0.001 μ and a state of hydration that makes for a stable suspension in pure water without the aid of a suspending agent. Unfortunately, some authors and some of the purveyors of proprietary barium sulfate mixtures either have failed to realize that confusion might occur or perhaps have wished to confuse. It would be well for radiologists as a group to put an end to such confusion by declining to use the term "colloidal" except for those barium sulfates that meet the classical standards of grain size and hydration. We would do well to refer to the dry preparations as "powdered mixtures of barium sulfate" and to the suspensions in mucilage, etc., as "homogenized suspensions of barium sulfate."

TESTS ON PROPRIETARY PREPARATIONS

With the help of the records of the Council on Pharmacy and Chemistry of the American Medical Association and the able assistance of my colleagues Dr. E. S. G. Barrón and Mr. Edward W. Dunklin of the section of chemistry of our department of medicine and of Mr. Paul F. Parker and Mr. Clifton J. Latiolais of our hospital pharmacy, it has been possible to check and disprove some of the actual claims and broad implications made in behalf of certain proprietary mixtures and suspensions. For example, one such suspension, described as "colloidal barium," on centrifuging yields a clear supernatant fluid that is not pure water as one would expect in a genuine suspension colloid but instead an aqueous solution of cellulose sulfate, saccharin, and flavoring material, while the barium sulfate that forms the sediment has a grain size many times larger than would be the case if it were truly colloidal. Another preparation that is distributed in dry form and is described as "colloidally stabilized micro barium sulfate" proves to be a mixture of powdered pectin and barium sulfate, the latter having a grain size 25% larger than that of the product we regularly buy from a manufacturing chemist as standard quality barium sulfate U. S. P. The measurements of grain size were done with a Patterson-Cawood calibrated reticule in the eyepiece of a microscope.

MISLABELING

It should not be necessary for physicians to go to all this effort in order to find out what they are buying and dispensing, and it would cease to be necessary if we and our societies and journals would take a firm stand against allowing the advertising of improperly labeled products or writing papers or accepting them for publication if they were based on work with unidentified materials. Mislabeling fosters careless thinking, and it is not in America alone that the error occurs. A leading German textbook of radiology[9] refers to a "colloidal barium," which presumably is merely ordinary barium sulfate mixed with a powdered gum, and a well-known British text declares[10]: "The colloidal preparation of barium sulfate now on the market will stay in suspension for one-half hour and may be used without any suspending agent." We have not had the opportunity to examine the product in question here but are strongly of the opinion that the reason why no suspending agent need be added is that one is already present as a powdered gum, presumably one of the celluloses.

GENUINE COLLOIDAL BARIUM SULFATE

Dr. Barrón assures me that it should be possible to prepare genuine colloidal barium sulfate by titrating a solution of barium chloride with sodium sulfate. The product thus prepared could be washed free of soluble barium, and if it were kept wet and not allowed to dry it would make a stable suspension in water alone without the aid of a suspending medium, though its barium content would be low and its stability vulnerable to contact with acid or alkali. It is conceivable that the addition of small amounts of such material to ordinary homogenized suspensions would improve their diagnostic properties, but there is no assurance of this, and as yet we have not had the opportunity to put the matter to clinical test.

SUSPENDING MEDIUMS

Ideal Suspension.—The ideal homogenized suspension for use as a barium enema should hold the bulk of the barium in suspension for long periods of time and yet deposit on the colon mucosa a thin barium sulfate film that will persist for from 10 to 15 minutes after the main portion of the enema has been expelled. The opacity and viscosity of the suspension should be capable of adjustment independently over a wide range, and its tendency to clog enema tips and lines of connecting tubing should be minimum. Suspensions for oral administration should be palatable in addition to having these other qualities.

Synthetic Gums.—In the preparation of homogenized suspensions of barium sulfate, the synthetic gums have many advantages over such substances as starch, pectin, acacia, agar, tragacanth, and gelatine; and, among the synthetics, sodium carboxymethylcellulose (C. M. C.) seems to be better than most.[11] It was developed in Germany in 1918 and is manufactured in this country by the Hercules Powder Company. It is extremely effective in holding barium sulfate in suspension, is nontoxic, and, unlike the natural gums, is not digested or precipitated by the acid or alkaline juices of the gastrointestinal tract. It is possible to mix powdered C. M. C. with dry barium sulfate and then add the water later as the material is to be used, but it is better to prepare an aqueous mucilage of the gum and then mix this with barium sulfate and water. At the moment our own practice is to have the C. M. C.-barium sulfate-water mixture prepared in our own pharmacy, run through a colloid mill there, and dispensed to the radiology department in one-gallon jugs ready for use.

Tannic Acid and Silicones.—We have had no personal experience with 1% tannic acid added to the enema mix-

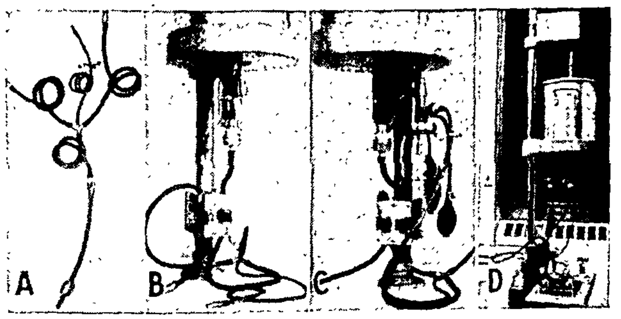
NEED FOR EXPERIMENTATION

Radiologists, chemists, and pharmacists should be encouraged to work at improving barium sulfate suspensions for oral and rectal administration, but their work will be most effective if it is stripped of every vestige of secrecy. Conceivably a precise control of the pH of the mixture might be conducive to the best results, and possibly a suspension in which the pH had been carefully adjusted and then buffered to resist the acidity of the gastric juice and the alkalinity of the intestine would be clinically advantageous. This is only a guess, however, and I am told that the gums themselves are such excellent buffering agents that it is unlikely that anything better could be found. I have omitted mention of the use of the iodized oils and colloidal thorium dioxide as gastrointestinal opaque mediums because the former have such a limited application and the latter is so impractical because of its radioactivity, to say nothing of its cost.



Barium enema apparatus. *A*, the enema tube assembly or harness. *B*, here the harness is being loaded into the apparatus. Pinchcock beneath the supply pot is closed. The crank of the four-way pinchcock is in the down or load position. The supply line has been inserted in the four-way cock and connected to the supply tank. The drainage line is in the process of being inserted but the gate that retains it is still open. *C*, both gates are now closed. The crank of the four-way pinchcock has been turned to the hold position, which pinches off both supply line and drainage line. The hand pinchcock beneath the supply pot has been opened. The air supply has been attached to its bracket and the air hose has been connected to the air supply. *D*, apparatus completely assembled at foot of fluoroscopic table. A sink beneath the supply pot catches the small amount of barium that is lost as harnesses are being changed between patients.

OBJECTIVES AND PROCEDURES

The techniques and criteria for detecting gross lesions of the colon have become reasonably well standardized and need not be considered here, but there is still debate as to the best means of detecting small polyps. Some radiologists prefer the air-contrast methods,[12] by which is meant the making of single or, preferably, stereoscopic roentgenograms after the mucosa of the bowel has been coated with barium sulfate and the lumen distended with air so that polyps show as rounded translucent masses thinly coated with barium. Others employ dilute suspen
sions of barium sulfate and subsequent filming, preferabl
stereoscopic, using radiation of moderate voltage,[illegible] b
which procedure polyps appear as negative shadows see
through the dilute barium that fills the lumen of the colo
Some of the published roentgenograms made by th
method are convincing indeed, but admittedly fluoro
copy is rendered somewhat more difficult because of t
low degree of contrast between the barium-filled loo
of bowel and the surrounding abdominal structur
Another method has been to employ barium suspensio
of normal opacity that show well on the fluorosco
screen when fluoroscopy is done at moderate voltage a
then to use higher voltage for making the films.[13] T
seems to be a logical approach, but at the moment f
radiologists are equipped with high-voltage diagno
machines. No doubt most of us agree with those w
believe that all of the methods have advantages and
advantages and that even a combination of all meth
will not suffice in all cases.

TECHNICAL DEVICES

Except where a maximum number of patients must
examined in a minimum amount of time, the simp
of devices suffice, but, where the volume of work is la
considerable time can be saved by employing spe
equipment. In 1936 Sarasin [14] described an appar
that enabled the radiologist to select at will full-stren
or diluted thorium dioxide for injection into the co
Injection was accomplished by compressed air at f
4.5 to 6 lb. to the square inch, and a valve that sele
either the full-strength medium or the diluted medium
under the control of a foot switch.

At the 1950 session of the American Medical Asso
tion in San Francisco, Dr. F. E. Templeton demonstr
and subsequently with Dr. E. A. Addington publish
description of an apparatus to facilitate filling and dr
ing the colon and introducing air after the bulk of
enema had been expelled.[12] These authors have supp
us with one of their instruments, and it has served as
starting point for apparatus of our own (figure). I
Templeton and Addington, we employ crank-oper
cams to operate pinchcocks that close or open line
rubber tubing, this unit constituting a four-way pi
cock, which in the first position allows barium to flow
the colon, in the second position closes both filling
draining lines, in the third position allows barium to
out of the colon into the sewer, and in the fourth posi
frees both lines so that the "gates" can be opened a
new harness of enema tip and connecting lines substit
for the one used for the previous patient. These ass
blies or harnesses are built up on a cross-shaped fit
that we make by welding a 3/16 in. aluminum nipple
the space between two of the limbs of a commercial 5
in. aluminum Y. This added nipple carries the air
and the neighboring 5/16 in. nipples are used, one
the supply of fresh barium suspension, the other
drainage. The third or common limb of the Y carries
enema tip, which is sometimes of metal, more freque
of the self-retaining rubber type (Bard No. 40). All th
lines are equipped with Schrader snap-on fittings so t
they may be quickly and easily attached to the air sup
the barium supply, and the drainage ejector.

The barium supply is stored in a 16-quart aluminum stockpot resting on a shelf that is clamped to a steel mast erected at the foot of the horizontal fluoroscope. Close to this mast and the foot of the table is a small sink equipped with a Penberthy ejector. The four-way pinchcock is buckled to a bracket or the vertical mast in a manner that allows rapid detachment for daily cleaning, and the shelf that carries the stockpot also provides support for the snap-on fitting in the barium supply line, a hand-operated pinchcock to shut off the supply during the changing of enema tube assemblies, and the glass jar, pump bulb, expansion bag, etc., that are used for inflating the colon.

The injection of barium can be started or stopped by turning the crank of the four-way pinchcock to the "fill" or to the "hold" position, and when it is desired that the enema be expelled this is done by turning the crank to the "drain" position and turning on the water to the Penberthy ejector. To inflate the colon one first drains it, then turns the crank of the four-way pinchcock to the hold position and opens the pinchcock on the air line. Now, by pumping the hand bulb, air is forced through the glass trap, through the small nipple of the cross, and through the enema tip into the bowel, backflow into the supply line and drainage line being prevented by the fact that with the handle at the hold position both of these lines are clamped.

To remove a harness that has been used by one patient in preparation for the insertion of a fresh one for the succeeding patient, one first closes the handcock beneath the stockpot and then turns the crank to the "load" position. The gates are now opened and the supply line disconnected from the fitting beneath the stockpot. When this has been done, fresh barium suspension will drain from the short run of supply line between the handcock and the Schrader fitting, but the amount is small, and most of it can be made to spill into the sink beneath. The air line likewise is disconnected at its Schrader fitting and last of all the drainage line from the Penberthy ejector. Of all three lines, this latter is the only one that becomes contaminated during the examination, and the apparatus has been designed so that with the exercise of reasonable care cross contamination will not occur from one patient to another.

MICROFILM SURVEYS OF COLON AFTER ORAL ADMINISTRATION OF BARIUM

The early work on examination of the colon following the oral administration of bismuth was so much less satisfactory than examination with the aid of the opaque enema that most radiologists are prejudiced against any return to the old method of attack. There is obvious need, however, for conducting routine photofluorographic surveys of the colon similar to those now established as standard procedures in the case of the lungs, and obviously for such work the barium cannot be introduced by rectum. As better homogenized suspensions of barium sulfate are produced, it seems increasingly possible that we may be able to devise mediums that will hold the barium in suspension throughout its entire passage through the alimentary tract, and in recent years the development of high-speed reflector cameras and more recently new fast refractors has brought the abdomen within the scope of the photofluorograph. An apparatus of this sort in which 70 mm. roll film is used has been under development by us for some time, was reported in September, 1952, at the annual meeting of the American Roentgen Ray Society, and presently will be published in the journal of that society. In the first model of our camera, the film-moving mechanism required the use of special thick-based film, and the loading and unloading of the film was a slow and difficult job. We have under construction a new film-moving mechanism in which film of standard thickness is used. It is extremely simple to load, and as soon as it is completed, we will begin routine colon surveys for symptomless polyps as well as other unsuspected lesions.

SUMMARY

Well-established and long-accepted techniques suffice for the radiologic detection of gross colon lesions, and the greatest contribution of radiology to the control of colon disease lies in this area. There is growing appreciation, however, of the importance of extending the colon x-ray examination to include the detection of very small lesions, particularly multiple polyps, and in this area there are difficulties that challenge existing techniques. Improvements are needed in the preparation of the patient, the formulation of barium suspensions, and the facilities for introducing and removing the barium and inflating the colon with air. Liquid diet and castor oil are preferable to cleansing enemas as preparation for colon examinations, and mucilage of sodium carboxymethylcellulose is a superior suspending agent for barium sulfate. An apparatus is described for facilitating the filling, draining, and insufflation of the colon in institutions where a maximum number of patients must be examined in a minimum of time. Where the volume of work is not large, simple accessories will yield equally satisfactory results. Routine small film surveys of the colon following the oral administration of barium suspensions eventually may be developed to the point where they approximate the usefulness of small film chest surveys.

950 E. 59th St.

Push-Button Diagnosticians.—I often think that if I were asked quickly to examine a group of men applying for the Diploma of the National Board of Internal Medicine I would test them on a patient suffering from a severe neurosis, bad migraine or mild psychosis, or the results of a little stroke, but with silent stones in the gallbladder, an old, long-healed "duodenal ulcer," a movable but silent and harmless right kidney, a harmless diverticulum of the duodenum, a silent diaphragmatic hernia, a colon covered with silent and harmless diverticula, some harmless cervical ribs, a silent myoma of the uterus, a large but harmless retrocecal appendix, a loud but harmless congenital heart murmur or a symptomless bundle-branch block.

The applicants who had enough clinical sense and wisdom not to grasp quickly and happily and confidently at the diagnostic straw offered them would be passed; the rest would be deferred. They, obviously, could not yet have attained into clinical wisdom. They would still be ordinary push-button diagnosticians, men like the head of a small clinic, who, on introducing me to his laboratory assistant, said: "Here's the woman who makes my diagnoses." How fearful I was that he was telling the truth!—W. C. Alvarez, M.D., On Disregarding Findings That Cannot Explain the Syndrome, *The New England Journal of Medicine*, July 30, 1953.

LIMITATIONS IN THE USE OF ROENTGEN EXAMINATION OF THE GASTROINTESTINAL TRACT

Paul C. Swenson, M.D.
and
Robert B. Jeffrey, M.D., Philadelphia

Within two years after Roentgen's discovery of the x-ray, Cannon studied the movements of the stomach and intestines of cats on the fluoroscopic screen after giving them food mixed with bismuth subnitrate. Shortly thereafter, Francis Williams applied a similar technique to human subjects, and an important and extremely useful method for examination of the digestive tract had its beginning. Today, the conventional fluoroscopic and radiographic examination of the gastrointestinal tract remains the safest and the most informative study of this system; however, this method of examination is by no means absolute, for there are many inherent limitations.

In many instances, varying with the anatomy of the subject examined and the conditions under which the examination is conducted, little credence should be attached to certain indefinite findings or to a negative study. Therefore, just as it is true that pathological change cannot be correctly interpreted when normal variants are not known, it is also true that any diagnostic study reaches its full value only when its limitations are well known and carefully considered.

There are several instances in which a properly conducted and interpreted roentgen examination of the gastrointestinal tract may yield results that are conflicting or fallacious. The first instance is a completely normal-appearing study when actually abnormality exists; the so-called subroentgenographic types of disease without apparent detectable structural or functional change in the gastrointestinal tract. A second instance is the finding of a structural or functional change, but failure to correctly interpret it. It is certainly not always possible to correctly interpret pathological change, although experience and the use of the best diagnostic aids reduce this error to a minimum. Not all findings are specific. They may be characteristic but not typical, in which case the clinical background must be carefully correlated. A third instance occurs in the study of specific areas of the gastrointestinal tract where it is difficult, at times, to demonstrate abnormalities even when they are known to be present. This fact is especially true in examination of the small intestine when, for example, a Meckel's diverticulum is known to be present and yet escapes detection in conventional studies.

TECHNIQUE

It is important to review the techniques and the actual mechanisms employed in studying the gastrointestinal tract. A suitable contrast medium, usually a suspension of barium sulfate or, in special instances, an opaque oil, can coat the inner or mucosal surface of the gastrointestinal tract. Any abnormality that is to be detected must produce some change in the accepted normal appearance of this inner surface of the hollow viscus under examination. The areas under examination are studied dynamically by fluoroscopy and are recorded for further careful study by properly exposed roentgenograms. All available variations of techniques should be employed to obtain the maximum of information. The use of skillful palpation, relief techniques, compression, double contrast study, and other special techniques, such as the addition of suspected allergens or psychic stimuli, may add to the informative value of the study.

The detection of physiological, anatomic, or functional change in many instances requires several different types of approach. A carefully recorded history and a brief but pertinent preliminary physical evaluation of the patient may suggest a variation of normal technique. The radiologist, like any other consultant, should have all the significant clinical information concerning the patient readily available. This is important in order to avoid excessive manipulation that may add to the very ill patient's distress or complicate his illness and is also important in other instances, for only when the radiologist has all the clinical information available can he be expected to intelligently interpret his findings.

The demonstration of any lesion in the gastrointestinal tract is dependent on its size. Every mucosal lesion has its intramural beginning, and until it (1) attains sufficient size for detection through a distortion of the mucosal silhouette by ulceration; (2) produces a filling defect; or (3) interferes with the intramural nervous mechanism, thereby affecting or producing apparent inflexibility, it is likely to remain undetected. However, a colonic neoplasm as small as 2 or 3 mm. may be demonstrated by a good double contrast roentgenogram, providing the colon has been properly prepared. The colon can be the most satisfactory part of the gastrointestinal tract for examination, provided good preparation has been accomplished, for one can control the amount and admixture of barium and air to produce the proper double contrast, if necessary, and, moreover, palpation can be carried out satisfactorily, particularly on the left side. It is, however, important to mention that the radiologist should not be responsible for diagnosis of diseases of the rectum. No x-ray procedure could, in any way, take the place of direct endoscopy in this location.

The gastrointestinal examination is worthy of the same preparation as a surgical procedure. If rigid attention to detail is carried out in this regard, more information will be forthcoming. The number of repeat examinations will be materially reduced, effecting a saving in time and expense to the radiologist, the institution that he may be serving, and the patient, to say nothing of the diminished radiation exposure to both the patient and the physician. In no other division of roentgen diagnosis

Read in the Symposium on Roentgen Examination of the Gastrointestinal Tract before the Section on Radiology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

are technical procedure and routine of examination more important than in the study of the gastrointestinal tract. Thus, the accuracy and success of the method depend on the knowledge, care, and skill of the physician conducting the examination, as well as the careful attention to details in the preparation of the patient. It should be the aim of the examiner to obtain the utmost information possible from each examination within the limits of the safety, comfort, and tolerance of the patient. Proper preparation makes such information easier to acquire.

Since we can visualize only the inside silhouette of the lumen of the organ being studied, and any effect noted must produce a change in its appearance, either structurally or functionally, a mass lesion will not become apparent until it has either attained sufficient size to change the mucosal surface by stretching, ulceration, or induration or produced a secondary functional change. Extralumenal masses can be detected if they are large enough and closely enough associated with the gastrointestinal tract to produce pressure effects on the lumenal silhouette. Moreover, the fluoroscopic manipulation will give one an idea of the relationship of the extralumenal masses to the gastrointestinal lumen.

Secondary manifestations that appear as gastrointestinal findings but are dependent on lesions adjacent to the gastrointestinal tract and its appendages are often detected, but they may be confusing. By interference with the blood supply, lymph drainage, or innervation, they produce changes in the appearance of the intestinal pattern. Localized motor changes appear reflexly and are often related to extralumenal lesions or the lesions at some distant point in the gastrointestinal tract.

The condition of any region at the time of study influences its roentgen appearance; for example, a narrow-necked diverticulum, by its very nature, may not fill, particularly if there is any associated inflammatory change, spasm, or edema. The regions may be filled with blood clot or fecal material and thus not permit filling with the opaque medium. In some instances, the neck of a diverticulum may be so wide that it will fail to hold the barium long enough to be detected. True diverticula, such as Meckel's diverticulum, empty as readily as the rest of the intestinal lumen. If bleeding occurs from such a lesion, it becomes more irritable; and, if inflamed, it becomes occluded.

Functional changes in the gastrointestinal tract are probably as common as functional changes in any other organ system in the body. They may be minimal in extent, or they may be so severe that they eventually produce extensive structural change. Emotional and allergic manifestations can produce marked change in the appearance of the bowel. Etiological diagnosis, in such instances, may be difficult to make because of similarity of pattern.

ESOPHAGUS

While barium studies of the esophagus may aid in specific cases, there are one or two limitations that must be noted. The first is the possibility of missing rather small lesions in the mucosal surface by not having several films with different degrees of filling. When there is no obstruction, the speed of passage of barium down the esophagus will often preclude the detection of a very small lesion without careful fluoroscopic study and serial films. Varicosities, unless they are very far advanced, may often escape detection, because peristalsis may "milk" them out; or they may be collapsed from recent hemorrhage. Therefore, careful fluoroscopic examination in all projections, with films made in various stages of filling, is usually necessary in order to see a small lesion. Even they may be missed, so that it can be said that varices can never be ruled out by radiological means. However, when lesions are large, the positive findings are obvious. Another rather annoying limitation of the examination of the esophagus is the difficulty of detecting small superficial ulceration associated with a diaphragmatic hernia or actual peptic ulceration.

STOMACH

In the stomach the greatest difficulty is at the upper end where palpation is not readily carried out. Here, even with good positioning and careful fluoroscopic control of roentgenographic projections it is easy to miss small lesions. This has been called the radiological "blind spot." Intramural lesions often give trouble unless careful fluoroscopy or a large series of films will show an apparent inflexibility of the stomach wall. Hyper-rugosity (increased mucosal folds) is a nonspecific finding that may be either inflammatory or the result of intramural infiltration. When there is doubt, early follow-up studies and gastroscopy are important adjuncts to the original roentgen examination of the stomach.

One of the greatest problems is distinguishing between a simple ulcer and an ulcer based on cancer or associated with a cancer. There are certain characteristic findings with the simple peptic ulcer, but there is a borderline type in which it is very difficult to tell whether there is an associated cancer. Unfortunately, no definite help is forthcoming from the gastroscopist in most of these cases. It is fortunate, however, that this borderline type is relatively small.

The radiologist is usually correct in his interpretation when he finds that the lesion appears radiographically benign. In questionable cases the patient can be put on a strict dietary regimen as a test of the lesion's benign nature (with early follow-up films), or exploration can be done immediately. An ulcer that is associated with cancer rarely decreases in size or disappears with a dietary regimen. The portion of stomach wall in which a malignant ulcer is present does not return to its usual normal flexibility, whereas almost always a complete restitution to normal occurs in a case of simple ulcer. The only crater associated with a cancer that we have seen disappear has been associated with the superficially spreading type of cancer. After the ulcer filled in, however, an area of apparent induration within the wall remained.

SMALL INTESTINE AND COLON

In the small intestine the intramural lesion that may produce very little effect on the mucosa of the wall is obviously very difficult to demonstrate. The obstruction appears relatively late, and the barium moves through rather rapidly; so that, unless careful fluoroscopy is carried out, lesions of this sort are easily missed. This is particularly true when a dumbbell variety of lesion is present in which the extralumenal mass may be larger than the intralumenal mass. The nonspecific finding of a swollen irregular mucosal pattern with segmentation and sometimes widening of the lumen can be caused by either local intramural changes or mesenteric involvement, in which case either the intramural nervous mechanism or the lymph-vascular and blood supply is affected. The blood supply and lymph-vascular drainage can be affected both by inflammatory change and by neoplasm. The pattern and transit time may be affected further by the following factors: (1) so-called allergic (food sensitivity) changes; (2) tumor, either intramural or mesenteric; (3) intramural inflammatory changes; and (4) extralumenal masses, which will affect the pattern. The findings in the obstructing lesions, which are often definitive, may sometimes be very difficult to interpret completely.

In the colon the size of the lesion is the only limitation (if careful preparation is carried out), since the examination can be better controlled than elsewhere in the gastrointestinal tract.

CONCLUSIONS

An acknowledgment of the limitations of the roentgen examination is no apology for it but rather renders it more valuable in the hands of the person who is attempting to interpret the findings. There are many limitations to every diagnostic procedure. In spite of the shortcomings, however, the roentgen examination remains at present the most important single diagnostic modality short of exploration and biopsy.

GASTRIC DIVERTICULA

A. W. Sommer, M.D.
and
W. A. Goodrich Jr., M.D., Temple, Texas

Gastric diverticula are relatively uncommon, but not actually rare. Many authors still stress the rarity of this abnormality, in spite of the fact that reported cases are now quite numerous. The first diverticulum to be diagnosed radiologically was reported by Brown [1] in 1916. With the increasingly frequent use of roentgen rays in gastrointestinal diagnosis, there has been a gradual accumulation of reported cases. Palmer [2] found reports of 412 cases in a recent very complete review of the literature. Since then, Eells and Simril [3] have reported 31 cases. In an extensive study of the literature to January, 1953, we were able to find reports of 449 valid cases. The diagnosis was based on roentgen examination alone in two-thirds of the cases. Relatively few were diagnosed gastroscopically. Thirty-eight diverticula were found incidentally at autopsy.[2] Undoubtedly, other diverticula have been diagnosed but have not been reported.

Kaufmann [4] has defined gastric diverticula as circumscribed, more or less rounded or bag-shaped protrusions from the lumen of the stomach containing all three layers. There has been much speculation regarding the origin of this abnormality and considerable confusion and inaccuracy in classification. Because this paper is limited to a consideration of the clinical and roentgenological characteristics of gastric diverticula, it is not necessary or desirable for us to become involved in this controversy.

SYMPTOMS

Symptoms due to diverticulum of the stomach may be lacking, and, when present, are usually vague and not characteristic. The most frequent complaint is epigastric discomfort, ranging from vague dyspepsia to severe, cramp-like pain in the epigastrium and the lower retrosternal region. Pain frequently occurs shortly after eating. It may be worse at night or when the patient is in the recumbent position. Nausea, vomiting, and dysphagia are occasional complaints. Symptoms are often intermittent, with relatively long remissions and sudden exacerbations. Uncomplicated gastric diverticula are frequently silent anomalies. In about one-third of the reported cases there were symptoms that were attributed to the diverticulum.

COMPLICATIONS

Bleeding is the commonest complication,[5] although serious hemorrhage is rare. Mucosal changes, such as erosion, gastritis, or superficial ulceration, were reported in one-third to one-half of the specimens that were examined. Aberrant pancreatic tissue was found in at least 15 specimens. Three instances of perforation of a diverticulum with hemorrhage into the peritoneal cavity have been reported.[6] There have been reports of gastric diverticula associated with both benign and malignant neoplasms. Some of these undoubtedly should have been classified as pseudodiverticula, because gastric neoplasms frequently develops central necrosis with the formation of a sac-like defect. In the reported cases, there was no definite proof that the diverticulum preceded the neoplasm. We have found no convincing evidence that carcinoma is more likely to occur in a diverticulum than in nondiverticular gastric tissue.

DIAGNOSIS

Most diverticula are discovered roentgenologically. Akerlund [8] proposed definite criteria for the roentgenologic diagnosis of diverticulum of the stomach in 1923. Sandstrom [9] and Reich [10] suggested additional diagnostic features. This has led to a better understanding of the abnormality and has increased the accuracy of diagnosis. When filled with barium, the diverticulum is seen as a smooth, sharply defined, round or oval sac that is attached to the stomach by a relatively narrow neck (fig. 1). Being thin-walled and pliable, the smooth outline persists, but the contour often varies with position and amount of filling. If the pouch is not completely filled with barium, an air-fluid level or a double contrast effect may be obtained (fig. 2). Change in position may result in emptying, but there frequently is retention of barium in the sac for many hours. At times, rugal markings can be seen in the mucosal lining of the diverticular neck (fig. 3). Tenderness is not present unless there is some complication.

Fig. 1.—Typical diverticulum 2 cm. in diameter arising from the posterior gastric wall about 3 cm. from the esophagogastric junction.

We were prompted to study this condition when we became aware of a marked increase in the frequency of our roentgen diagnosis of gastric diverticula. In 1952 the diagnosis was made nine times in 5,110 patients who were subjected to roentgen examination of the stomach, giving an incidence of one diverticulum discovered per 568 examinations. In the previous 10 years only eight cases were found in 44,870 such examinations, an incidence of one in 5,610 examinations. The significance of this variation in the discovery rate will be discussed. A total of 21 diverticula were diagnosed during a period of 26 years (table 1).

ANALYSIS OF OUR CASES

Location and Size.—Twenty of the 21 diverticula in this series were situated at the cardiac end of the stomach, arising from the posterior wall 3 to 5 cm. from the esophagogastric junction. One was located in the prepyloric region, on the greater curvature side, about 2 cm. from the pylorus (table 2). Half of the diverticula were from 2 to 3 cm. in diameter (range 1 to 5 cm.) Barium was retained in the diverticulum in 53% of the patients having subsequent roentgenograms.

TABLE 1.—*Number and Incidence of Gastric Diverticula Seen at Scott and White Clinic, 1927-1952*

	1952	1942-1951	1927-1941	Total
No. of diverticula discovered....	9	8	4	21
No. of patients subjected to stomach examinations.........	5,110	44,870	33,788	83,768
Incidence	1:568	1:5,610	1:8,447	1:3,990

Age and Sex.—The ages of the patients in our series ranged from 23 to 77 years; 11 were 50 years of age or older, and 10 were 23 to 50 years. More than half, or 60%, of the patients were women.

Relation of Symptoms to Diverticulum.—Only six patients had symptoms that we attributed to the gastric diverticulum. Pain was present in each of these patients, with radiation to the lower retrosternal region in three instances. In two patients, the pain was severer at night, and three had aggravation of distress after meals. There

COMPLICATIONS

Bleeding is the commonest complication,[5] althoug serious hemorrhage is rare. Mucosal changes, such a erosion, gastritis, or superficial ulceration, were reporte in one-third to one-half of the specimens that were exam ined. Aberrant pancreatic tissue was found in at least 1 specimens. Three instances of perforation of a diverticu lum with hemorrhage into the peritoneal cavity have bee reported.[6] There have been reports of gastric diverticul associated with both benign and malignant neoplasms Some of these undoubtedly should have been classified a pseudodiverticula, because gastric neoplasms frequentl develops central necrosis with the formation of a sac-lik defect. In the reported cases, there was no definite proo that the diverticulum preceded the neoplasm. We hav found no convincing evidence that carcinoma is mor likely to occur in a diverticulum than in nondiverticula gastric tissue.

From the Department of Radiology of the Scott and White Clinic (Dr. Sommer); Resident in Radiology, Scott and White Memorial Hospitals and the Scott, Sherwood and Brindley Foundation (Dr. Goodrich).

DIAGNOSIS

Most diverticula are discovered roentgenologically. Akerlund[8] proposed definite criteria for the roentgenologic diagnosis of diverticulum of the stomach in 1923. Sandstrom[9] and Reich[10] suggested additional diagnostic features. This has led to a better understanding of the abnormality and has increased the accuracy of diagnosis. When filled with barium, the diverticulum is seen as a smooth, sharply defined, round or oval sac that is attached to the stomach by a relatively narrow neck (fig. 1). Being thin-walled and pliable, the smooth outline persists, but the contour often varies with position and amount of filling. If the pouch is not completely filled with barium, an air-fluid level or a double contrast effect may be obtained (fig. 2). Change in position may result in emptying, but there frequently is retention of barium in the sac for many hours. At times, rugal markings can be seen in the mucosal lining of the diverticular neck (fig. 3). Tenderness is not present unless there is some complication.

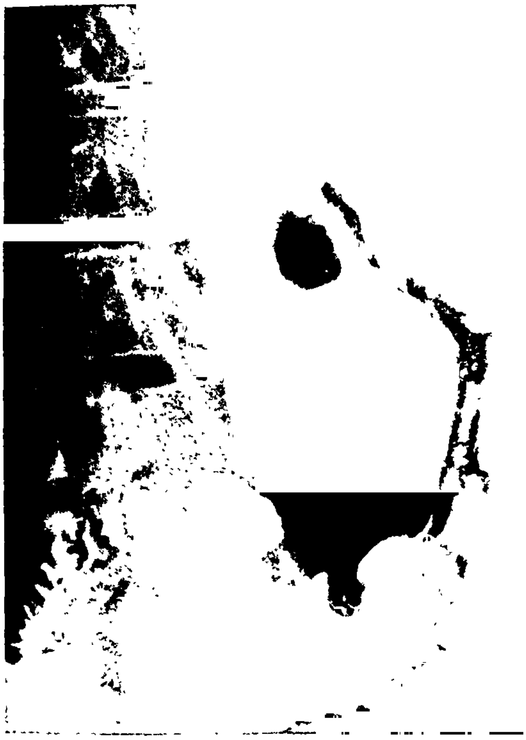

Fig. 1.—Typical diverticulum 2 cm. in diameter arising from the posterior gastric wall about 3 cm. from the esophagogastric junction.

We were prompted to study this condition when we became aware of a marked increase in the frequency of our roentgen diagnosis of gastric diverticula. In 1952 the diagnosis was made nine times in 5,110 patients who were subjected to roentgen examination of the stomach, giving an incidence of one diverticulum discovered per 568 examinations. In the previous 10 years only eight cases were found in 44,870 such examinations, an incidence of one in 5,610 examinations. The significance of this variation in the discovery rate will be discussed. A total of 21 diverticula were diagnosed during a period of 26 years (table 1).

ANALYSIS OF OUR CASES

Location and Size.—Twenty of the 21 diverticula in this series were situated at the cardiac end of the stomach, arising from the posterior wall 3 to 5 cm. from the esophagogastric junction. One was located in the prepyloric region, on the greater curvature side, about 2 cm. from the pylorus (table 2). Half of the diverticula were from 2 to 3 cm. in diameter (range 1 to 5 cm.) Barium was retained in the diverticulum in 53% of the patients having subsequent roentgenograms.

TABLE 1.—*Number and Incidence of Gastric Diverticula Seen at Scott and White Clinic, 1927-1952*

	1952	1942-1951	1927-1941	Total
No. of diverticula discovered....	9	8	4	21
No. of patients subjected to stomach examinations.........	5,110	44,870	33,788	83,768
Incidence	1:568	1:5,610	1:8,447	1:3,990

Age and Sex.—The ages of the patients in our series ranged from 23 to 77 years; 11 were 50 years of age or older, and 10 were 23 to 50 years. More than half, or 60%, of the patients were women.

Relation of Symptoms to Diverticulum.—Only six patients had symptoms that we attributed to the gastric diverticulum. Pain was present in each of these patients, with radiation to the lower retrosternal region in three instances. In two patients, the pain was severer at night, and three had aggravation of distress after meals. There

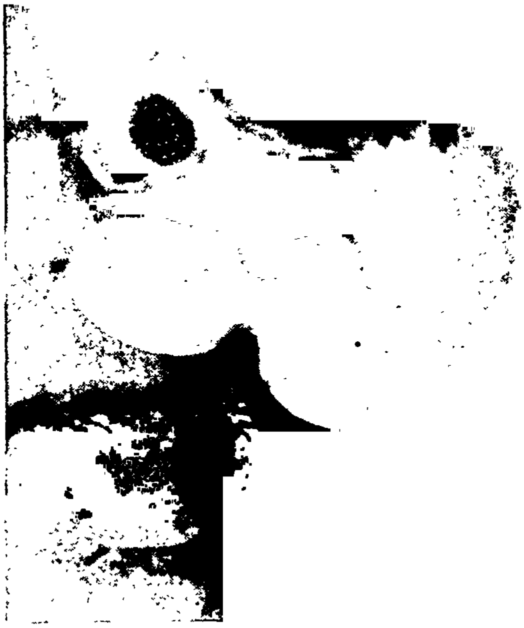

Fig. 2.—Diverticulum 4 cm. in diameter in the usual location at the cardia, illustrating double contrast effect.

was evidence of bleeding in three patients; one vomited blood and two had tarry stools (table 2). Three patients who are still under observation, have symptoms that may be due to the diverticulum (table 2).

Twelve patients either had no symptoms or had symptoms that could be attributed to causes other than the diverticulum. Seven patients had associated duodenal ulcer. One had cholelithiasis, and acute appendicitis developed in one while he was under observation. Both of these patients obtained relief of their symptoms after surgery, although the diverticulum was not disturbed in either instance. One patient with a diverticulum adjacent to the cardia, discovered 25 years ago, has never had symptoms. This patient has been examined periodically and the diverticulum has remained unchanged.

Treatment.—Three of our patients were subjected to surgery for gastric diverticulum (table 3). Thus 14% of patients with gastric diverticula received surgical treatment for their condition. Following are reports of these three cases:-

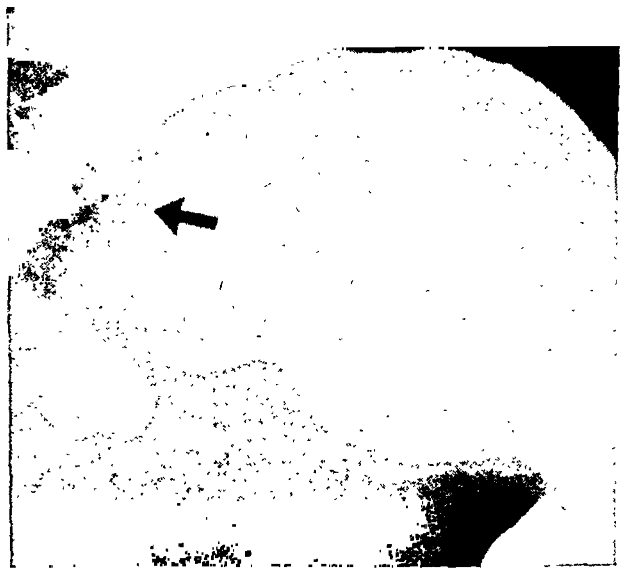

Fig. 3.—Diverticulum 2½ cm. in diameter adjacent to the cardia. The black arrow points to the esophageal orifice. Normal mucosal markings can be seen in the narrow neck.

REPORT OF CASES

Case 1.—A 50-year-old man reported to this clinic because of burning pain and a feeling of fulness in the epigastrium. Pain radiated to the lower retrosternal region and, when severe, would seem to shut off his breath. Belching and vomiting always relieved the discomfort. Roentgen examination of the stomach showed a diverticulum about 5 cm. in diameter arising from the posterior gastric wall about 4 cm. from the esophageal opening. There was also slight deformity of the duodenal cap with no evidence of crater or obstruction.

Because of the severity of the symptoms, an operation was performed. The surgeon found slight scarring of the duodenal cap but no indications of active duodenal ulcer. The diverticulum was resected. Histopathological study revealed normal mucosa, moderate diffuse lymphocytic infiltration of the submucosa, and moderate thinning of the muscularis. Four months later, a roentgenologic examination of the stomach showed slight irregularity of the stomach wall at the operative site and slight deformity of the duodenal cap similar to that seen preoperatively. A verbal report from the patient four years postoperatively was "no complaints since the operation."

Case 2.—A 58-year-old man reported to this clinic because of indigestion and recurring spells of burning pain in the epigastrium of 15 years' duration. Food and alkalies had given no relief. For one day, four weeks before admission, he passed black, tarry stools. Three days before admission, he began to pass copious tarry stools and complained of weakness. His appearance on admission indicated extensive blood loss.

Results of laboratory studies were as follows: hemoglobi level of 9 gm. per 100 cc.; red blood cell count, 2,960,000 and feces, tarry, with positive test for blood. The first roentgenologic examination of the stomach revealed no abnormalities. Roentgenograms of the abdomen made 24 hours late showed no residual barium. When the stomach examination was repeated several days later, a diverticulum, measuring 2½ cm. in diameter, was found arising from the posterior gastric wall 2 cm. from the esophageal orifice. Barium was still present in the diverticulum 18 hours later. The esophagus, stomach, and entire small bowel otherwise appeared normal. Roentgenologic examination of the colon showed no abnormalities.

Because of continued blood loss, an operation was advised. Two blood transfusions were given, and exploratory laparotomy was done. No lesions other than the diverticulum were found. The diverticulum was situated in the location described on the roentgenogram. Because of the technical difficulties encountered, the surgeon inverted the diverticulum and ligated blood vessels adjacent to the base.

Table 2.—*Descriptive Data in Twenty-One Cases of Gastri Diverticula*

	No. of Patients	Percentage
Location at cardia	20	95
Location at pylorus	1	5
Men	8	40
Women	13	60
Retention of barium	7 (out of 13)	54
Symptoms due to the diverticulum	6	28
Chief symptoms:		
Epigastric pain	6	..
Pain worse when recumbent	2	..
Pain worse after eating	3	..
Retrosternal radiation	3	..
Nausea and vomiting	2	..
Tarry stool	2	..
Vomiting of blood	1	..
Symptoms possibly due to diverticulum	3	14
Symptoms could not be attributed to diverticulum	12	57
Associated disease:		
Duodenal ulcer	7	..

60-69	3	5-5.9	1
70-79	1		

Table 3.—*Treatment in Twenty-One Cases of Gastric Diverticula*

Treatment	No. of Patients
Appendectomy	1
Cholecystectomy	1
Medical (or no treatment)	9
Associated duodenal ulcer	7
Surgical	3
Resected at cardia	(1)
Resected at pylorus	(1)
Inverted at cardia	(1)

We have no definite proof that the diverticulum was the source of the bleeding in this case, but no other bleeding source could be found. During the year that has elapsed since the operation, there has been no further hemorrhage.

CASE 3.—A 32-year-old man presented himself because of epigastric pain. Nine years before admission, a diagnosis of duodenal ulcer was made elsewhere. He responded fairly well to medical treatment until about three or four weeks before admission. Vomiting and severe epigastric pains made him seek admission to the hospital.

Roentgenologic examination of the stomach showed a marked deformity of the duodenal cap, with a small crater in the base of the cap and a round, sac-like projection, about 1½ cm. in size, arising from the prepyloric region of the stomach on the greater curvature side (fig. 4). The radiologic diagnosis was (1) duodenal ulcer with crater and (2) gastric diverticulum. We attributed his symptoms to the duodenal ulcer rather than to the diverticulum.

Operation was advised because of the presence of the duodenal ulcer and to confirm the presence of a gastric diverticulum. The distal three-fourths of the stomach was resected. The diverticulum was found as described in the roentgenologist's report. Histopathological study showed it to consist of all three layers found in a normal gastric wall with no evidence of mucosal change or aberrant pancreatic tissue.

COMMENT

A better understanding of this subject is possible if gastric diverticula are divided into groups on the basis of location.

1. *Diverticula Adjacent to Cardia.*—At least 75% of all gastric diverticula arise from the posterior wall 3 to 5 cm. from the entrance of the esophagus. They are usually asymptomatic and seldom give rise to complications.

2. *Diverticula Adjacent to Pylorus.*—About 15% of gastric diverticula occur near the pylorus. Diagnosis is difficult, and complications are not uncommon.

3. *Diverticula in Other Portions of Stomach.*—Diverticula in other parts of the stomach comprise a relatively small group. Diverticula are seldom found more than a few centimeters from the cardia or the pylorus. Diagnosis is difficult, and complications are common.

Each group may be considered almost a separate entity, with a remarkable uniformity of the clinical and roentgenological characteristics of all the diverticula in that group. This uniformity is especially striking in the diverticula that occur close to the cardia. Almost all of them arise from a specific portion of the posterior wall and, except for slight variation in size, are almost identical in appearance. We have been impressed by the failure of these diverticula to fill when the patient is examined in the upright position. Various authors state that filling will usually occur with the first swallow of barium. In our series only 4 of the 20 diverticula in the cardiac end of the stomach filled when the patient was standing; the rest failed to fill until the patient was placed in the supine or the Trendelenberg position. In over half of our cases, the left posterior oblique position, with the patient recumbent, was the only projection that permitted adequate roentgenographic demonstration of the pouch. Since most fluoroscopic examinations are done with the patient upright and the usual routine is to obtain roentgenograms in the posterioranterior and the right anterior oblique projections, many of these diverticula are not visualized. Pendergrass [11] made this observation in 1931.

At times, a diverticulum is not visualized because it is filled with retained food or secretions that prevent entrance of the barium. It is also possible for a diverticulum with a small orifice to remain distended with gas in spite of all efforts to fill it with barium. In this instance the gas pocket adjacent to the barium-filled stomach may be seen during fluoroscopy or on the roentgenogram. Thus, a diverticulum that filled readily at one examination may not be seen at a subsequent examination because it is filled with food or secretion, or it may appear as a gas shadow if trapped gas in the pouch prevents entrance of the barium.

The gradual increase in the discovery rate of gastric diverticula in our clinic is largely due to a renewed interest in diaphragmatic hernia. It became apparent soon after we started our diaphragmatic hernia studies that we were discovering gastric diverticula more frequently. Fluoroscopic examination in various positions, careful positioning of patients for roentgenograms, and frequent reexamination resulted in better visualization of defects in the cardiac end of the stomach. When it became apparent that diverticula adjacent to the cardia usually do not fill with barium when the patient is examined in the upright position, we began to repeat examination whenever the roentgenogram revealed any irregularity of or an unusual gas shadow near the cardiac region. We were able to make the diagnosis of diverticulum in six instances because roentgenograms, made as part of the first examination, aroused our suspicion and made us request reexamination.

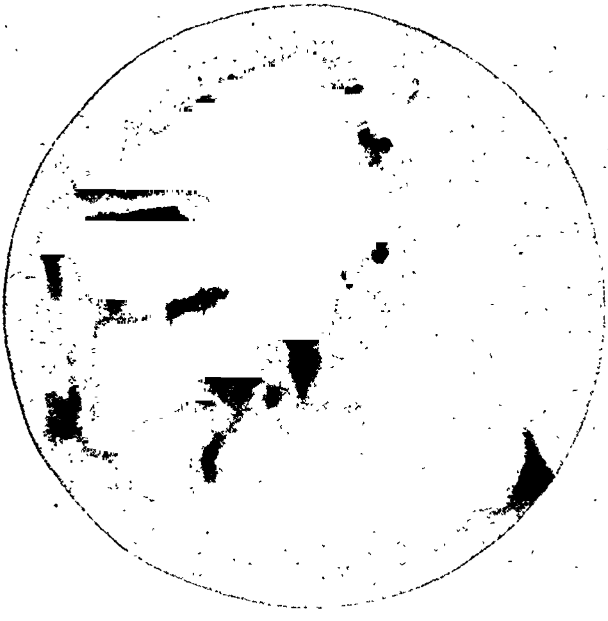

Fig. 4 (case 3).—Diverticulum 1½ cm. in diameter adjacent to the pylorus, proved surgically. All three layers of the stomach were present and there was no aberrant pancreatic tissue. (The photograph was retouched.)

Diverticula adjacent to the cardia may be difficult to fill with barium, but, once visualized, are not likely to be diagnostic problems. The characteristic location, smooth, rounded outline, and relatively narrow neck make recognition easy. Benign gastric ulcer seldom occurs in this portion of the stomach. When it does occur near the cardia, it may be confused with a diverticulum, but, usually, the ulcer defect can be recognized by the broad base, the failure to retain barium, and the absence of the smooth, rounded outline so typical of a diverticulum. Spasm and tenderness are frequently absent in gastric ulcers in this location. In some instances, it may be necessary to place the patient on a medical ulcer regimen and do repeated examinations to detect evidences of healing.

---

[11] Pendergrass, E. P.: Diverticulum of Upper End of Stomach, S. Clin. North America 11:1493-1496 (Dec.) 1931.

An ulcerating carcinoma near the cardia may result in a pouch-like defect that bears a superficial resemblance to a diverticulum. The defect is almost always irregular, however, and a meniscus sign is frequently present. The neck is usually broad and irregular, and the mucosa adjacent to the orifice is not normal.

Varices in the cardiac end of the stomach are rarely a source of confusion. Defects due to varices are usually multiple, producing a general irregularity of the mucosal pattern in the cardiac region. There are almost always associated esophageal varicosities. A cascade type of stomach, a small diaphragmatic hernia or a long subdiaphragmatic esophagus, may simulate a diverticulum, but examination of the patient in various positions will usually make differentiation possible.

We have encountered a previously undescribed differentiation problem. Following operative repair of a hiatus hernia, a contraction ring of scar tissue may remain to constrict the stomach near the cardia. The resulting deformity may resemble a diverticulum, but the neck is apt to be rather broad and the esophagus can be seen to enter directly into the pouch.

Usually uncomplicated diverticula near the cardia cause no symptoms, but they may be responsible for baffling complaints. Six of the 20 patients in this series with diverticula near the cardia had symptoms that could be attributed to the abnormality. Relief of symptoms can generally be obtained by simple therapeutic measures. Frequently, the patient himself has discovered a procedure or a remedy that gives him relief. A bland, low roughage diet, antacids, and postural drainage of the sac have been advocated. Operation is indicated when any complication such as hemorrhage, severe pain, or perforation occurs.

Diverticula adjacent to the pylorus present more serious diagnostic difficulties. This is not a common location for a diverticulum, since only 15% of the reported diverticula were near the pylorus. Other pathological conditions, many of them serious, occur in this portion of the stomach much more frequently. It is not uncommon for these to produce defects that appear on the roentgenogram as a sac-like defect. Benign ulcer crater, perforated ulcer with accessory pocket formation, ulcerating carcinoma, and syphilis of the stomach present the most serious diagnostic problems. An additional difficulty arises from the fact that diverticula near the pylorus frequently contain islands of pancreatic tissue. This may alter the appearance enough to make recognition of the diverticulum exceedingly difficult. Diverticula in this location frequently present a confusing picture clinically and radiologically, and it is seldom possible to make a definite radiologic diagnosis of diverticulum of the pyloric end of the stomach. Consequences of misdiagnosis are so serious that every diagnosis of diverticulum in the distal end of the stomach should be confirmed by operation.

Diverticula rarely occur more than a few centimeters from the cardia or the pylorus. Only 8 to 10% of the reported diverticula were found in the pars media and the fundus of the stomach. Some of these were definitely due to perigastric adhesions, classified by some authors as acquired, true diverticula. Relatively few verified, uncomplicated diverticula, located some distance from the cardia or the pylorus, have been reported. Some of the unverified ones probably were false diverticula. Diagnosis is always difficult. It is practically impossible to make a radiologic diagnosis of diverticulum when the pouch i not located near the cardia or the pylorus. Gastroscopic examination or surgical exploration must be done to ascertain the true nature of the abnormality.

Clinicians have generally accepted the radiologic diagnosis of diverticulum of the colon or the duodenum, bu have been hesitant about accepting the diagnosis of diverticulum of the stomach. This may be partly due to the confusion that has resulted from the inclusion of diverticulum-like deformities, designated as false diverticula in some classifications. Definite criteria have been established that permit a high degree of accuracy in the radiologic diagnosis of gastric diverticulum. If only thos diverticula that fulfill these criteria, or are proved a operation or autopsy, are accepted, a more accurate analysis of the material will be possible. This will permi better evaluation of the accuracy of the roentgen diagnosis of gastric diverticulum and aid in establishing thi abnormality as a positive or negative factor in gastrointestinal complaints.

SUMMARY AND CONCLUSIONS

The literature concerning gastric diverticula is reviewed. The characteristics of gastric diverticula are discussed, with emphasis on roentgen diagnosis. Finding in 21 previously unreported cases of gastric diverticula seen at the Scott and White Clinic during the past 20 years are reviewed.

The following conclusions may be made:

1. Diagnosis is almost solely the responsibility of the radiologist.
2. Gastric diverticula show a remarkable tendency to localize at a specific point near the esophagogastric junction.
3. Many diverticula probably escape detection because of failure to fill with barium.

410 Lamar Dr. (Dr. Sommer).

Sudden Death in Infancy.—For a series of infants *observed to die* suddenly while in apparent good health, in whom the gross necropsy findings were inconclusive, histologic lesions are described consisting of inflammatory changes in the respiratory tract, vascular changes, focal cellular infiltrations in many organs, and reaction of the lymphatic tissues. These lesions are identical with those we have previously reported in babies *found dead* in whom mechanical suffocation is often alleged as the cause of death. The present study offers additional evidence for the previous conclusions; namely, that in infants, fulminating respiratory disease is the common cause of sudden, unexpected, and apparently unexplained *death.*—J. Werne, M.D., and I. Garrow, M.D., Sudden Apparently Unexplained Death During Infancy, *The American Journal of Pathology,* September-October, 1953.

PROGRAM FOR THE DETECTION OF COLONIC AND RECTAL POLYPS

Cesare Gianturco, M.D.
and
George A. Miller, M.D., Urbana, Ill.

The clinical significance of polyps of the large intestine has been discussed by many authors, and it is now generally accepted that many cancers develop from originally benign adenomatous polyps. For this reason, the recognition of these small growths is important for the prevention and cure of early malignant lesions of the large intestine. The recognition of colonic and rectal polyps [illegible] on objective methods of examination. Since many polyps are located in the terminal 25 cm. of the intestine, routine employment of the proctoscope by the general practitioner in adult patients has been strongly recommended.

In diagnostic centers, the responsibility is greater and the visual inspection of the accessible large bowel should be supplemented by x-ray examination of the colon. This may pose peculiar problems of organization and timing. These problems can be solved through the cooperation of the clinical departments involved. The program of polyp detection developed at the Carle Clinic involved the cooperation of the departments of internal medicine, surgery, proctology, and radiology. After several trials and errors, the following scheme was finally adopted:

1. Most adult patients undergoing a "general examination" receive a roentgen study of the colon by means of "high voltage radiography." 2. Adult patients without definite symptoms are examined by rectoscopy in addition to the roentgen study of the colon. This examination is a proctoscopy limited to the rectum and is performed in the x-ray department just prior to the x-ray work. Rectoscopy does not interfere with the x-ray examination of the colon and is essentially painless. 3. Adult patients complaining of bleeding from the rectum or of anal disease receive, in addition to the roentgen examination of the colon, proctosigmoidoscopy of the terminal 25 cm. in the department of proctology. Because of the insufflation of air necessary, proctosigmoidoscopic examinations are not done on the same day as the x-ray work.

TECHNIQUES OF EXAMINATION

High Voltage Radiography.—This technique is based on the observation that radiographic opacity changes with the voltage employed. A barium mixture that is fully opaque at fluoroscopy at 80 kv. usually consists of one volume of barium powder suspended in four volumes of water. When the colon is radiographed at 120 kv., this barium mixture becomes transparent and radiolucent objects, if present, are visible as negative shadows (see the figure).

The examination begins with fluoroscopy of the rectosigmoid area, during which the barium is allowed to reach the splenic flexure, carrying with it any gas or fecal material that may have been left in the lower intestine. During this phase of the examination, the patient is rotated from side to side to determine the best positions to prevent overlapping of the sigmoid loops. Fluoroscopy is then stopped and two 10 in. by 12 in. high voltage films of the sigmoid are exposed with the overhead tube with the patient in two different positions. This radiographic "uncoiling" of the sigmoid is important because in the oblique positions fluoroscopic visibility is poor, and a large percentage of colonic lesions are found in this area. The study of the sigmoid should be completed before the examination of the upper colon is proceeded with, because barium in the cecum or in the terminal ileum may obscure the sigmoid loops.

After the sigmoid has been studied and filmed, fluoroscopy is resumed, allowing the barium to fill the whole colon and to spill into the terminal ileum. The enema tube is withdrawn and the machine reset for high voltage radiography, one 14 in. by 17 in. film being made with the patient prone and another with the patient supine with the overhead tube. Spot films may be taken for both flexures and the cecal area. The purpose of all this positioning is to change the pattern of any gas or fecal material that may be present within the bowel and to furnish multiple checks on radiolucent shadows that may appear on the films. Such shadows may be caused by growths, by air bubbles, and by fecal material. Fecal material is mottled, irregular, and mobile. Air bubbles tend to be multiple, round, or oval and change shape and position in the various films. Growths may be of any shape, but their appearance and position remain essentially unchanged in the different views. If a persistent radiolucent shadow is found, the examination is repeated on another day for final confirmation of diagnosis.

In adequately prepared patients, high voltage radiography is capable of demonstrating growths as small as 2 mm. in diameter. Its sensitivity is greatest in the transverse, descending, and sigmoid colon. The technique is less satisfactory in the cecum and rectum because of the greater cross section of the bowel.

Rectoscopy.—Rectoscopy is preceded by a cleansing enema, the patients having received 2 oz. (60 cc.) of castor oil the night before. The proctoscope is introduced as far as possible (usually to a depth of from 15 to 18 cm.) into the rectum and sigmoid without insufflation of air with the patient in the prone Trendelenburg position. Occasionally one may reach the full depth of 25 cm. After the examination is completed and while the proctoscope is being withdrawn, the patient is asked to "take a deep breath and strain." This maneuver expels the air that has entered the rectum because of the position of the patient. The expulsion of this air is essential to avoid

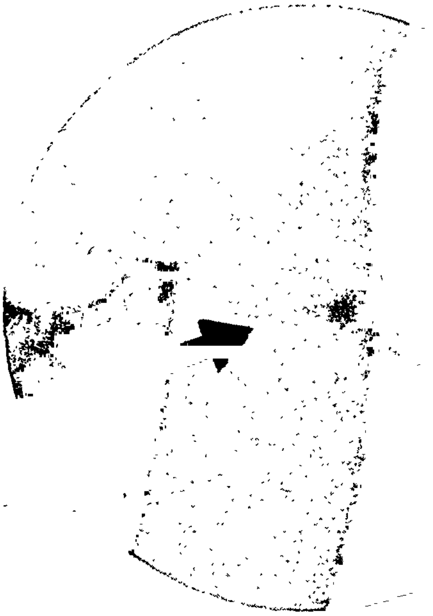
Read in the Symposium on Roentgen Examination of the Gastrointestinal Tract before the Section on Radiology at the 102nd Meeting of the American Medical Association, New York, June 3, 1953.

interference with the x-ray work that is to follow. Another enema is given after the rectoscopy.

Proctosigmoidoscopy.—Proctosigmoidoscopy requires insufflation of air and for this reason is done on the day before the roentgen study of the colon. The patients are prepared with enemas, and the technique is that ordinarily used by the proctologists.

RESULTS

The results (see the table) of this coordinated program may be stated as follows: High voltage radiography of the colon was used routinely during a period of 24 months. In the course of 3,351 examinations, 79 patients were found to have 92 polyps. Of these 79 patients, 21 complained of rectal bleeding. Nine polyps were found to be malignant.



Single polyp 1 cm. in diameter seen in the descending portion of the colon.

Results of Program for Polyp Detection

Total no. of high voltage x-ray examinations	3,351	
No. of patients with polyps	79	(2.3%)
No. of polyps found	92	
No. of polyps less than 1 cm. in diameter	38	
No. of polyps more than 1 cm. in diameter	54	
Location of polyps		
Right side of colon	8	
Sigmoid colon	44	
Descending colon	34	
Rectum	6	
No. of asymptomatic polyps	58	
No. of bleeding polyps	21	
No. of polyps removed surgically	43	
Adenomatous polyps	32	
Carcinomatous polyps	9	
Lipomas	1	
Lymphosarcomas	1	
Total no. of proctosigmoidoscopic examinations in presence of symptoms	500	
No. of patients with polyps	60	(12%)
No. of polyps found	69	
No. of carcinomatous polyps	5	
Total no. of rectoscopic examinations in absence of symptoms	1,000	
No. of patients with polyps	58	(5.8%)
No. of polyps	64	
Total no. of carcinomatous polyps in entire series	14	

One thousand rectoscopic examinations performe during a period of nine months in asymptomatic patient disclosed the presence of 64 polyps in 58 patients. On a average, these polyps were much smaller than those dis covered on roentgenograms and were fulgurated witho performance of biopsies. None of these polyps cause noticeable bleeding.

The available data on proctosigmoidoscopy cover period of 10 months and include 500 such examination Rogers reports the finding of 69 polyps in 60 patients. these 60 patients, 20 complained of bleeding. Five poly were malignant.

SUMMARY AND CONCLUSIONS

Our program of polyp detection revealed 14 cases early and curable carcinoma of the colon during t course of 4,851 visual and x-ray examinations. Polyps the colon and rectum are relatively frequent in adul Many of these growths are asymptomatic. Their mal nant potentialities make them clinically important. T routine use of the proctoscope by the general practitio should lead to the discovery of polyps in from 8 to 10 of adult patients. A coordinated program consisting visual examinations and sensitive roentgen studies is pr tical in diagnostic centers. This program should lead the discovery of polyps in from 10 to 15% of adult p tients regardless of symptoms.

602 W. University Ave. (Dr. Gianturco).

Clubfoot.—The child born with a clubfoot should be s immediately by the orthopedic surgeon, and unless there some contraindication, treatment should be started at o The nurse is instructed in careful, gentle manipulation of foot, correcting the varus only. As soon as the pediatric feels that it is safe to apply a plaster of Paris dressing should be done, usually at the age of 4 or 5 days. T dressing is allowed to remain on for a period of ten days, a which it is removed and a second plaster applied. The dr ing extends from the base of the toes to above the knee j (midthigh) with the knee in flexion, thus avoiding the sibility of kicking off the plaster by the child. The plaster dr ing at this stage corrects only the varus of the foot, no atte being made to correct the equinus, as this would tend produce a so-called rocker sole. After the second plaster been applied, considerable correction has usually taken pl so that it is possible to apply a Denis Browne splint to b feet, allowing the child free knee joint motion, and avoiding atrophy of the calf muscles. With the Denis Bro splint the child obtains considerable correction of the formity because of the activity of the lower extremities. With the adjustments of the Denis Browne splints it is possi to obtain full correction of the varus, after which the atten of the surgeon must be directed toward correction of equinus; following correction of the equinus, one must certain that the correction is maintained by the application proper footwear. X-ray examination of the foot to determ the relationship between the astragalus and the os calcis the anteroposterior plane is of considerable value in decid when to start the correction of the equinus. If the nor relationship between these two bones is not established bef an attempt is made to correct the equinus, a rocker sole develop.—H. C. Fett, M.D., Orthopedic Management of F Disorders, *Surgical Clinics of North America,* October, 1953.

RADIOLOGICAL EXAMINATION IN ORGANIC DISEASES OF SMALL INTESTINE

Ross Golden, M.D.
and
Pablo L. Morales, M.D., New York

Organic disease of the small intestine, as well as functional disorders, may be the source of abdominal symptoms. X-ray examinations, when properly conducted, have proved to be of great value in the detection of these conditions. Occasional statements in the medical literature indicate that this fact is not widely recognized.

The records of 199 patients of the Presbyterian Hospital in New York with verified organic disease of the jejunum and ileum were analyzed. In 168 of them information suitable for the studies described was found. The purpose of this paper is to review the incidence of certain physical characteristics of these diseases that may be demonstrable by x-ray examination and to investigate the ability of the x-ray method to disclose evidence of these lesions as shown by the records in this series of cases. No attempt was made to compare or correlate the data from this series with those of other published series of cases. The diagnoses in this series were as follows: regional enteritis in 74 cases, tuberculous enteritis in 12, primary carcinoma in 23, lymphoma in 20; other malignant neoplasms in 8; carcinoid in 14, and benign tumors in 21.

SYMPTOMS

Organic disease of the small intestine may produce one or more of three symptoms. These symptoms are (1) bleeding, (2) diarrhea, or (3) abdominal pain.

Bleeding.—Table 1 gives the incidence of bleeding in this series. If the bleeding was sufficient to be recognized by the color of the stool, it was classed as gross. In some instances the record shows no evidence that tests for occult blood in the stool were done. In some cases an operation was done as an emergency before a complete clinical study was made. In others, the reason is not evident. Pallor, low hemoglobin and red blood cell counts, hypoproteinemia, and edema of the ankles were occasionally encountered.

* The figures in the parentheses indicate the total number of cases in which the conditions were found.

Diarrhea.—Diarrhea (table 1) was recorded as an important symptom in more than half of the cases of regional enteritis and a quarter of those of tuberculous enteritis. It was uncommon with the neoplasms. It was a prominent symptom in four cases of infiltrating lymphosarcoma that involved the entire length of the small intestine.

Examination of colon...........	..	..	..	..	..	1	..
No examination..	10	4	4	7	2	6	6

Abdominal Pain.—Abdominal pain may be localized in the periumbilical or right lower quadrant regions (table 1). In 10 cases of regional enteritis both locations were mentioned. Disease of the ileocecal region may cause epigastric pain or distress. In 74 of the 168 cases the pain was recorded as unlocalized and in 33 no pain was mentioned. The absence of pain was found in a larger proportion of the cases of carcinoid than in the other conditions.

METHODS OF EXAMINATION

Three methods of examination were used: (1) study of the small intestine, (2) use of the small intestinal enema, and (3) examination with the Miller-Abbott tube (table 2).

Study of Small Intestine.—The small intestine study is the routine method. The patient is given a suspension of barium sulfate by mouth after fasting overnight and a succession of films of the abdomen is made at half hourly intervals. For years we used 4 oz. (120 cc.) of barium sulfate in 5 oz. (150 cc.) of isotonic sodium chloride solution. This was satisfactory in most cases. Under certain conditions not yet well understood, flocculation occurs, the crystals of this salt seem to adhere to each other, and the mucosal surface of the intestine is not well shown (Frazer, French, and Thompson [1]). For this reason, in

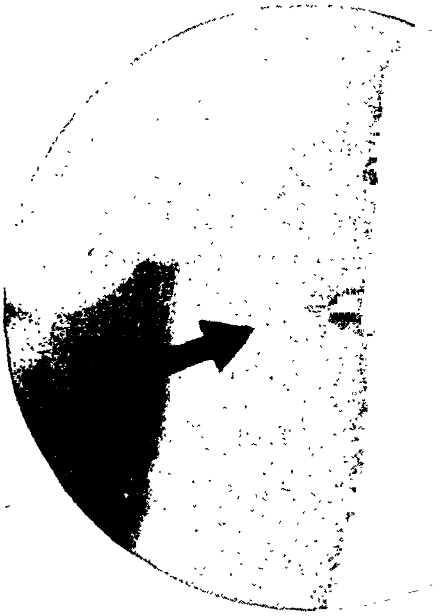
interference with the x-ray work that is to follow. Another enema is given after the rectoscopy.

Proctosigmoidoscopy.—Proctosigmoidoscopy requires insufflation of air and for this reason is done on the day before the roentgen study of the colon. The patients are prepared with enemas, and the technique is that ordinarily used by the proctologists.

RESULTS

The results (see the table) of this coordinated program may be stated as follows: High voltage radiography of the colon was used routinely during a period of 24 months. In the course of 3,351 examinations, 79 patients were found to have 92 polyps. Of these 79 patients, 21



Single polyp 1 cm. in diameter seen in the descending portion of the colon.

complained of rectal bleeding. Nine polyps were found t be malignant.

One thousand rectoscopic examinations performe during a period of nine months in asymptomatic patient disclosed the presence of 64 polyps in 58 patients. On a average, these polyps were much smaller than those discovered on roentgenograms and were fulgurated withou performance of biopsies. None of these polyps cause noticeable bleeding.

The available data on proctosigmoidoscopy cover period of 10 months and include 500 such examination Rogers reports the finding of 69 polyps in 60 patients. C these 60 patients, 20 complained of bleeding. Five polyp were malignant.

SUMMARY AND CONCLUSIONS

Our program of polyp detection revealed 14 cases early and curable carcinoma of the colon during th course of 4,851 visual and x-ray examinations. Polyps the colon and rectum are relatively frequent in adult Many of these growths are asymptomatic. Their malignant potentialities make them clinically important. Th routine use of the proctoscope by the general practition should lead to the discovery of polyps in from 8 to 10 of adult patients. A coordinated program consisting visual examinations and sensitive roentgen studies is practical in diagnostic centers. This program should lead t the discovery of polyps in from 10 to 15% of adult patients regardless of symptoms.

602 W. University Ave. (Dr. Gianturco).

Clubfoot.—The child born with a clubfoot should be see immediately by the orthopedic surgeon, and unless there some contraindication, treatment should be started at onc The nurse is instructed in careful, gentle manipulation of th foot, correcting the varus only. As soon as the pediatricia feels that it is safe to apply a plaster of Paris dressing th should be done, usually at the age of 4 or 5 days. Th dressing is allowed to remain on for a period of ten days, aft which it is removed and a second plaster applied. The dressing extends from the base of the toes to above the knee joi (midthigh) with the knee in flexion, thus avoiding the possibility of kicking off the plaster by the child. The plaster dressing at this stage corrects only the varus of the foot, no attem being made to correct the equinus, as this would tend t produce a so-called rocker sole. After the second plaster h been applied, considerable correction has usually taken plac so that it is possible to apply a Denis Browne splint to bot feet, allowing the child free knee joint motion, and als avoiding atrophy of the calf muscles. With the Denis Brown splint the child obtains considerable correction of the deformity because of the activity of the lower extremities. . . With the adjustments of the Denis Browne splints it is possibl to obtain full correction of the varus, after which the attentio of the surgeon must be directed toward correction of th equinus; following correction of the equinus, one must b certain that the correction is maintained by the application o proper footwear. X-ray examination of the foot to determin the relationship between the astragalus and the os calcis i the anteroposterior plane is of considerable value in decidin when to start the correction of the equinus. If the norma relationship between these two bones is not established befor an attempt is made to correct the equinus, a rocker sole wil develop.—H. C. common with many radiologists, we have more recently been using a nonflocculating preparation of barium sulfate. In most of the cases in this series, however, the examinations were done with barium sulfate suspended in isotonic sodium chloride solution.

The films are processed as soon as they are made and are inspected immediately. Fluoroscopic examinations with spot films are done as indicated. Pressure films of the terminal ileum and cecum are an important routine part of every examination.

Small Intestine Enema.—The small intestine enema is accomplished by passing a tube into the proximal jejunum and injecting through the tube a barium sulfate preparation until the entire small intestine is filled, while the patient is on a fluoroscopic table equipped for spot film work. This method was advocated by Schatzki.[2] In our series we used it on only one patient (carcinoid). With a nonflocculating suspension of barium sulfate the intestinal walls can be satisfactorily outlined in the great majority of cases. This makes the small intestine enema necessary only after the routine study has failed to show an abnormality in cases where it seems that organic disease is probably present, e. g., when bleeding is present.

Miller-Abbott Tube.—The Miller-Abbott tube is used in ileus cases. It deflates the intestine, and, when its progress is arrested, a barium sulfate preparation is injected and spot films are made to establish the character of the obstruction. This tube may also be used in cases of intestinal bleeding, if the routine method has failed to demonstrate a lesion. As the tube passes down in the intestine, specimens of intestinal contents are withdrawn at intervals and are tested for occult blood. A barium sulfate preparation can be injected through the tube at any point in the procedure and the area at and beyond the tip studied on the fluoroscopic table with spot films.

The difference between the small intestine enema and the Miller-Abbott tube study, as the terms are used in this paper, is that in the former the opaque material is injected into the proximal jejunum until the entire small intestine is filled. In the latter the tube is allowed to pass down until it is arrested or until a positive blood test of the withdrawn intestinal contents is obtained, and then opaque material is injected.

TABLE 3.—*Location of Disease of Small Intestine*

Terminal ileum..	47	8	2	4	..	2	2
Ileocecal valve...	25	6	2	4	..	1	..

* In some cases multiple lesions were present in both jejunum and ileum.

In 39 of the 168 cases, no x-ray examination was done at the Presbyterian Hospital. In some instances the patient was admitted and operated on without complete study because of symptoms consistent with acute appendicitis or ileus. In other instances the patient had had an examination elsewhere recently.

LOCATION OF DISEASE

The sites of these lesions in the intestine are shown i table 3. The ease of detection of disease of the intestin by x-ray examination is in part related to its location Lesions in the upper loops of jejunum and in the termina ileum are more easily demonstrated than those in th lower loops of jejunum and in the middle loops of th ileum which usually lie low in the pelvis. In most person the terminal 10 to 15 cm. of the ileum rise out of the pelvi into the right iliac fossae and therefore can be easil examined. In persons with a cecum lying low in the pelvi the shadow of the terminal ileum may be separated fro the other loops with great difficulty and recorded only c spot films made with the patient rotated, with or witho pressure.

TABLE 4.—*Length of Lesion in Small Intestine*

Length, Cm.	Regional Enteritis (74)	Tuberculosis (12)	Carcinoma (23)	Lymphoma (20)	Other Malignant Neoplasms (8)	Carcinoid (14)	Benig Tumo (21)
Less than 2......	0	2	3	3	1	4	3
2-4..	3	1	11	7	4	8	14
5-6.......... ...	2	1	5	4	1	1	3
7-8	2	3	3	1	0	0	1
9-10	5	2	1	0	1	0	0
11-15.	10	2	0	0	1	0	0
16-25	19	0	0	1	0	1	0
25-50	22	0	0	0	0	0	0
More than 50....	11	1	0	4	0	0	0

Inflammations, lymphosarcomas, carcinoids, and be nign tumors were found much more frequently in th ileum than in the jejunum. Carcinomas were much mo frequent in the jejunum. The figures in table 3 were o tained from the descriptions of the specimens given in th pathologists' reports.

LENGTH OF LESIONS

Organic disease of the small intestine, in the gre majority of cases, produces a narrowing of the lumen. I malignant tumors and in some inflammations the muco is destroyed or at least the folds are obliterated. This pr duces an easily detected modification of the bariu shadow if the opaque material accurately outlines th wall and if the involved loop is not obscured by overlyi barium shadows.

The figures given in table 4 are taken from the p thologists' reports. The majority (90%) of the lesions regional enteritis in this series were more than 8 cm. length. More than half of the tuberculous lesions were le than 8 cm. in length. The majority of the neoplast lesions were small enough to produce defects in th barium shadow of 6 cm. or less. The four cases of lymph sarcoma with long lesions had the infiltrating type of th disease, which extended along the wall of the entire sma intestine.

NUMBER OF LESIONS

Lesions of the small intestine may be either single o multiple. If two lesions were separated by a length o normal intestinal wall, they were classed as multiple. I the 168 cases of this series, lesions were single in 128 an multiple in 44. Only 1 of the 23 carcinomas was multiple. Carcinoids, lymphosarcomas, certain other malignant tumors, and inflammatory lesions are not infrequently multiple. The number of cases in which single and multiple lesions were found is shown in table 5.

---

[2] Schatzki, R.: Small Intestinal Enema, Am. J. Roentgenol. 50: 743, 1943.

In 4 of the 168 cases, two different diseases were demonstrated in the intestine by the pathologist. Two patients had benign polyps with a carcinoma, one had tuberculosis of the ileum in the midst of which was a small carcinoma, and a patient with a lipoma of the ileum also had nine, apparently asymptomatic, carcinoids.

RESULTS OF X-RAY EXAMINATION

In 133 of the 168 cases for which records were examined, one or more of the types of examination discussed were done at the Presbyterian Hospital. It was possible to show evidence of an abnormality in 121 of these 133 cases, or about 90% (table 6).

COMMENT

The x-ray examinations in these cases were done by a relatively large number of persons, of a wide range of age and experience. Many were done by residents under supervision. No attempt is made to estimate the accuracy of the interpretation of the abnormality in terms of the histological character of the disease. Usually, but not always, inflammations were distinguishable from neoplastic disease. Not infrequently different members of the staff of the radiological service disagreed as to the nature of the lesion. The mere fact of the demonstration of an abnormality in the small intestine, in addition to negative results of examinations of the stomach, duodenum, and large intestine, sufficed to solve the clinical problem. For example, in the presence of intestinal bleeding, evidence of an abnormality in the small intestine consistent with a neoplasm is sufficient to warrant a surgical investigation, as in the following case.

REPORT OF A CASE

A 56-year-old physician bled from the intestine for about five weeks. His hemoglobin level was 9 gm. per 100 cc. The stomach, duodenum, and colon were not abnormal on x-ray examination. A small intestine study disclosed evidence of a defect about 5 to 6 cm. in length in the barium shado a loop of ileum low in the pelvis. This could have been duced by a polypoid neoplasm of any type. After resection i was *found to be an inverted Meckel's* diverticulum with an ulcer at its tip.

The large number of films that are made in a routine small intestine study can be most accurately inspected by putting all of them side by side in chronological order on large viewing cabinets. In this way the eye of the observer can move quickly from one film to another and can most easily detect abnormalities in the barium shadow.

The benign tumors encountered in this series were 7 leiomyomas, 1 enterocystoma, 3 fibromas, 2 endometriomas, 2 adenomatous polyps, 1 hemangioma, and 5 lipomas.

A few miscellaneous conditions were encountered that were not included in this statistical study. They included simple ulcer of the ileum with cicatricial stenosis; irradiation damage; acquired diverticulum with ulceration; Meckel's diverticulum with ulcer; and inverted Meckel's diverticulum with ulcer (in the case described). We intend to study further certain details of the abnormalities produced by these lesions as shown by x-ray examination and to report them in a subsequent communication.

SUMMARY

A statistical study of 168 cases of organic lesions of the jejunum and ileum is presented. Bleeding was relatively uncommon in regional enteritis, while it occurred in one-third to one-half of the cases of intestinal tuberculosis and neoplastic lesions. Diarrhea was frequently encountered in the inflammations but was uncommon with the primary neoplasms. Abdominal pain was present in a large proportion of all of the cases, but it was not recorded in 8 of the 14 carcinoids.

All of the lesions found in this series of cases occurred much more frequently in the ileum except the carcinomas, which were localized more frequently in the jejunum. Four of the 168 patients had two different diseases in the small intestine at the same time. With the exception of the carcinomas, multiple lesions were found in from one-quarter to one-half of the cases, particularly carcinoids and lymphomas.

In 133 of the 168 cases x-ray examinations were made, and evidence of an abnormality consistent with an organic lesion was demonstrated in 121 (90%). The most practical method of x-ray examination is the small intestine study following the ingestion of a nonflocculating suspension of barium sulfate. The Miller-Abbott tube and the small intestine enema are useful in selected cases. These methods, when properly carried out, will disclose evidence of organic disease of the small intestine in a high percentage of cases.

Diabetes Mellitus Among the Aged.—Available data indicate that the prevalence of diabetes mellitus increases as age increases. . . . Diabetes mellitus needs emphasis in programs concerned with the health of older people. Surveys and detection drives concerned with diabetes case-findings should attempt whenever possible to reach the older person.—C. L. Krag, M.D., The Prevalence of Diabetes Mellitus Among the Aged Tested in a Community Diabetes Program, *Journal of Gerontology*, July, 1953.

EMERGENCY CARE OF *SUSPECTED* MIDDLE MENINGEAL HEMORRHAGE

TECHNICAL SUGGESTIONS FOR THE GENERAL SURGEON

R. B. Raney, M.D., Aidan A. Raney, M.D.
and
Eric W. Peterson, M.D., Los Angeles

Hemorrhage from the middle meningeal artery is relatively uncommon as a complication of head injury, but, because of the large number of head injuries that occur, this lesion is encountered fairly often. When a patient with such a condition reaches a well-equipped neurosurgical center without delay, conditions are optimum for its recognition and treatment. Many patients, however, are necessarily admitted to hospitals having few if any neurosurgical facilities, and any procedure by which cerebral compression may be kept from increasing can well be lifesaving. In such a situation a general surgeon with standard equipment may ligate the external carotid artery on the side of the suspected hemorrhage, a measure that enables the patient to be maintained in status quo until adequate neurosurgical treatment can be instituted.

Therapeutic trepanation of the skull for relief of hemorrhage after head injury actually is an ancient procedure; however, successful surgery for extradural hemorrhage dates back only about 200 years to Hill,[1] a Scottish surgeon who operated on two patients. Bell,[2] in 1816, gave a hypothesis of the pathogenesis of extradural hematoma and described its experimental proof. Hutchinson,[3] in analyzing the clinical signs accompanying this lesion, drew attention to the dilatation of the pupil, especially on the homolateral side. Olsen [4] described early constriction of the homolateral pupil as a forerunner to dilatation. Jacobson,[5] in 1885, gave an extensive and accurate account of the clinical syndrome, which remains classical. More recently, many authors [6] have reported their experiences with extradural hemorrhage and have stressed t rapidity with which this syndrome may advance once is established. It is evident that even in skilled hands it a serious and urgent problem, and there remains a ne for emphasizing technical methods for the manageme of these cases, especially in circumstances that may ari in an emergency.

The problem of management resolves itself into, fir recognition of the probable lesion and, second, relief cerebral compression before irreparable damage tak place. When a patient with a head injury who has do well for a few hours begins to show signs of increas intracranial pressure, drowsiness, and bradycardia, t possibility of middle meningeal hemorrhage must be co sidered. The most reliable localizing signs are pupilla changes, which almost invariably are on the side of t hemorrhaging vessel. Early pupillary constriction is cor mon; dilatation occurs later. A fracture through t middle meningeal groove, if present, is also a reliab localizing sign. Hemiparesis, either contralateral homolateral, may be present.

Ligation of the external carotid artery on the appr priate side does no harm, and if hemorrhage from t middle meningeal artery actually is taking place, th procedure can be expected to stop further hemorrhag Severe cerebral compression then may be relieved by simple trephine opening and suction. The patient then ca be moved a considerable distance, if necessary, in relati safety to facilities where definitive management can offered.

TECHNIQUE OF LIGATION

The relatively simple technique of ligation of the e ternal carotid artery is illustrated in the figure. This ac junct to treatment is not new, having been described b others [7]; however, it seems worthy of reemphasis becaus of its practical value. By means of a skin-line incision the level of the upper border of the thyroid cartilage, th medial border of the sternocleidomastoid muscle is ex posed and retracted to give access to the carotid sheat Palpation for the common carotid leads rapidly to i recognition; it is isolated by blunt dissection. The vesse is then easily followed upward to the bifurcation. Th positive recognition of the external carotid is made by th following criteria [8]: first, it is medial to the internal ca rotid immediately above the bifurcation and, second, i alone gives off branches in the neck. Once it is recognized a silk ligature may easily be passed around it and tied.

In order to stress this feature of treatment, a case i reported below in which such a ligation was carried ou with highly satisfactory results. It should be emphasized that ligation accomplished two important steps in the treatment: (1) the control of further hemorrhage, and (2) the evacuation of the clot and relief of compression

without the need for hemostatic packing. The patient then could be safely transferred to another hospital adequately equipped for major intracranial surgery.

REPORT OF A CASE

The patient, a carpenter 54 years old, was struck on the right side of the head by a timber. He felt that the injury was minor and wanted to continue working. His superintendent, however, insisted that he be examined. Roentgenograms of the skull revealed a linear fracture in the right parietal region. Because of the fracture the patient was sent to a local hospital for observation. The following morning he was found to be slightly hemiparetic on the left side; he complained of headache and possibly was a little drowsy. A few hours later he lapsed into coma. His respirations became embarrassed. He was cold, clammy, and cyanotic. It was at this stage that we first had the opportunity of examining the patient. His right pupil was widely dilated. He failed to respond to stimulation. His pulse had left the bradycardia stage and was irregular and rapid.

Unfortunately, the patient was in a hospital that was not equipped for intracranial surgery, and it was obvious that he could not tolerate the delay necessary for transfer to a better-equipped hospital. Consequently, the right external carotid artery was ligated in the neck with a small emergency dissecting set to stop further hemorrhage. An emergency craniotomy was then done with an old hand trephine that was available. An enormous extradural hemorrhage was encountered, which was partially evacuated with a tonsil suction apparatus, reducing the pressure. The patient's condition immediately improved. The carotid ligation had stopped bleeding, so a small pack was placed in the wound and the head was bandaged. With an intratracheal catheter in situ and the patient's condition improved, he was transferred safely to another hospital, where the operation was completed with the aid of adequate neurosurgical equipment and personnel.

Prior to closure of the wound, the brain and subarachnoid space were reexpanded by saline solution introduced into the lumbar spinal canal. After these procedures the patient responded promptly, and his subsequent convalescence was uneventful despite the fact that at its maximum depression the dura had been separated 5 cm. from the inner table of the skull.

COMMENT

The numerous published reports and the experiences of many neurosurgeons attest to the therapeutic problems attendant on this mechanically rather simple but frequently disastrous lesion. In this case we feel that the ligation of the external carotid artery played a major role in the successful outcome.

The typical syndrome of progressive depression of the level of consciousness, with associated homolateral third nerve changes and contralateral or homolateral paralysis of the extremities, whether or not complete in all its features, demands the arrest of further hemorrhage and evacuation of the hematoma. The middle meningeal artery is the commonest source of the bleeding in the most serious and rapidly progressive of these lesions.[9] Skull roentgenograms often reveal a fracture that traverses the groove of the middle meningeal artery. Ligation of the corresponding external carotid artery in the neck offers a direct and simple means to control bleeding. The ligation should always be on the side of the pupil showing pathological change, on the side of the fracture, or both. If there is any doubt about the pupillary sign, both external carotid arteries may be ligated. Their ligation will not cause material harm, whereas failure to ligate the external carotid artery on the side of the hemorrhaging meningeal artery will almost always lead rapidly to a fatal issue. By stopping the hemorrhage in this manner, time is provided for further study and for transfer of the patient to a place where there are more ideal conditions for removal of existing hematoma by craniotomy.

SUMMARY

Hemorrhage from the middle meningeal artery, while occurring in a small percentage of head injuries, is encountered with relative frequency because of the large number of head injuries. The syndrome of middle meningeal hemorrhage, once established, usually continues to develop rapidly to a fatal issue unless relieved. Because of the widespread occurrence of head injuries and the urgency for immediate admission of the patient to the nearest hospital, these lesions often are found where conditions are not ideally suited for neurosurgical intervention. Ligation of the external carotid artery in the neck on the side of the hemorrhage is a procedure worthy of consideration under such conditions. It can provide more time for transferring the patient to a location better suited for definitive neurosurgical care and often may be a lifesaving measure.

Airplane Travel and Diseases of the Lungs.—Patients with mild asthma may safely fly. However, a patient who is subject to frequent attacks should not fly. . . . Pneumothorax is a definite contraindication to airplane travel. . . . Going up in an airplane causes expansion of air in the pleural space. . . . Flying is especially hazardous for those who have pneumothorax complicated by adhesions, as they may break, causing hemorrhage, or they may pull hard enough to rip the surface of the lung. Additional air may then enter the pneumothorax and dangerously increase its size. . . . Patients who have recently hemorrhaged from the lungs should postpone flying, because of the danger of reopening the blood vessel. Pulmonary cavities are another hazard. They contain air which expands in flight. When air can escape from the cavity the danger is minimal. However, if bronchial obstruction is present, air is trapped in the cavity and, in expanding, may tear the walls of the cavity or injure a blood vessel with subsequent serious bleeding.—S. Kreinin, M.D., Which Patients May Fly, *GP (Journal American Academy of General Practice)*, August, 1953.

EMERGENCY CARE OF SUSPECTED MIDDLE MENINGEAL HEMORRHAGE

TECHNICAL SUGGESTIONS FOR THE GENERAL SURGEON

R. B. Raney, M.D., Aidan A. Raney, M.D.
and
Eric W. Peterson, M.D., Los Angeles

Hemorrhage from the middle meningeal artery is relatively uncommon as a complication of head injury, but, because of the large number of head injuries that occur, this lesion is encountered fairly often. When a patient with such a condition reaches a well-equipped neurosurgical center without delay, conditions are optimum for its recognition and treatment. Many patients, however, are necessarily admitted to hospitals having few if any neurosurgical facilities, and any procedure by which cerebral compression may be kept from increasing can well be lifesaving. In such a situation a general surgeon with standard equipment may ligate the external carotid artery on the side of the suspected hemorrhage, a measure that enables the patient to be maintained in status quo until adequate neurosurgical treatment can be instituted.

Therapeutic trepanation of the skull for relief of hemorrhage after head injury actually is an ancient procedure; however, successful surgery for extradural hemorrhage dates back only about 200 years to Hill,[1] a Scottish surgeon who operated on two patients. Bell,[2] in 1816, gave a hypothesis of the pathogenesis of extradural hematoma and described its experimental proof. Hutchinson,[3] in analyzing the clinical signs accompanying this lesion, drew attention to the dilatation of the pupil, especially on the homolateral side. Olsen [4] described early constriction of the homolateral pupil as a forerunner to dilatation. Jacobson,[5] in 1885, gave an extensive and accurate account of the clinical syndrome, which remains classical. More recently, many authors [6] have reported their experiences with extradural hemorrhage and have stressed t rapidity with which this syndrome may advance once is established. It is evident that even in skilled hands it a serious and urgent problem, and there remains a ne for emphasizing technical methods for the manageme of these cases, especially in circumstances that may ari in an emergency.

The problem of management resolves itself into, fir recognition of the probable lesion and, second, relief cerebral compression before irreparable damage tak place. When a patient with a head injury who has do well for a few hours begins to show signs of increas intracranial pressure, drowsiness, and bradycardia, t possibility of middle meningeal hemorrhage must be co sidered. The most reliable localizing signs are pupilla changes, which almost invariably are on the side of t hemorrhaging vessel. Early pupillary constriction is cor mon; dilatation occurs later. A fracture through t middle meningeal groove, if present, is also a reliab localizing sign. Hemiparesis, either contralateral homolateral, may be present.

Ligation of the external carotid artery on the appr priate side does no harm, and if hemorrhage from t middle meningeal artery actually is taking place, th procedure can be expected to stop further hemorrhag Severe cerebral compression then may be relieved by simple trephine opening and suction. The patient then ca be moved a considerable distance, if necessary, in relati safety to facilities where definitive management can b offered.

TECHNIQUE OF LIGATION

The relatively simple technique of ligation of the ex ternal carotid artery is illustrated in the figure. This ac junct to treatment is not new, having been described b others [7]; however, it seems worthy of reemphasis becaus of its practical value. By means of a skin-line incision a the level of the upper border of the thyroid cartilage, th medial border of the sternocleidomastoid muscle is ex posed and retracted to give access to the carotid sheath Palpation for the common carotid leads rapidly to it recognition; it is isolated by blunt dissection. The vesse is then easily followed upward to the bifurcation. Th positive recognition of the external carotid is made by th following criteria [8]: first, it is medial to the internal ca rotid immediately above the bifurcation and, second, i alone gives off branches in the neck. Once it is recognized a silk ligature may easily be passed around it and tied.

In order to stress this feature of treatment, a case is reported below in which such a ligation was carried out with highly satisfactory results. It should be emphasized that ligation accomplished two important steps in the treatment: (1) the control of further hemorrhage, and (2) the evacuation of the clot and relief of compression

CARCINOMA OF THE TESTES

Col. James C. Kimbrough (MC), U. S. Army
and
Major Ferris E. Cook Jr. (MC), U. S. Air Force

Although almost all tumors of the testes are malignant, such tumors are rare. These tumors, however, present a particularly serious problem in the armed forces inasmuch as they are found chiefly in young adults from 20 to 40 years of age, with the peak occurrence in the late 20's. Few cases have been reported in the very young or in the aged. Since the incidence in the armed forces personnel is about 1 in 10,000, the mobilization of more than 10 million men in the early 1940's gave physicians an opportunity to treat and observe a large number of patients with cancer of the testis. In 1946, Friedman and Moore[1] reported 922 cases—a startling number—from the Armed Forces Institute of Pathology.

ETIOLOGY

As in cancer of other organs, the etiology of cancer of the testis is obscure. Since these tumors occur at the period of greatest sexual vigor, it is probable that such activity and the increase in testicular hormones may be factors. The possible importance of testicular hormones in this role is further demonstrated by the favorable influence of castration on late metastases in some patients. There is no evidence that trauma has etiological importance. It has been estimated that cancer occurs 20 to 40 times oftener in undescended testes than in the normal organ. These statistics are difficult to evaluate and often unconvincing.

PATHOLOGY

There has been considerable confusion in the classification of tumors of the testes. The following classification of structural types and the percentage of occurrence given by Friedman and Moore[1] is simple and understandable and gives the physician a better working basis than does the more elaborate nomenclature. They estimate that 35% are seminomas, 35% teratocarcinomas, 19% embryonal carcinomas, 7% teratomas, 3% miscellaneous tumors, and 1% interstitial tumors.

Malignant tumors of the testis arise from totipotent sex cells. The monodermal forms of these growths represent one-sided developments of tridermal teratomas. The tumors are often mixed in type; in the event that one type predominates, the minor elements may not be found on pathological examination. A seminoma that appears monodermal may contain subversive elements of embryonal carcinoma, chorioepithelioma, or other highly malignant forms. These unrecognized elements not infrequently metastasize independently of the seminoma.

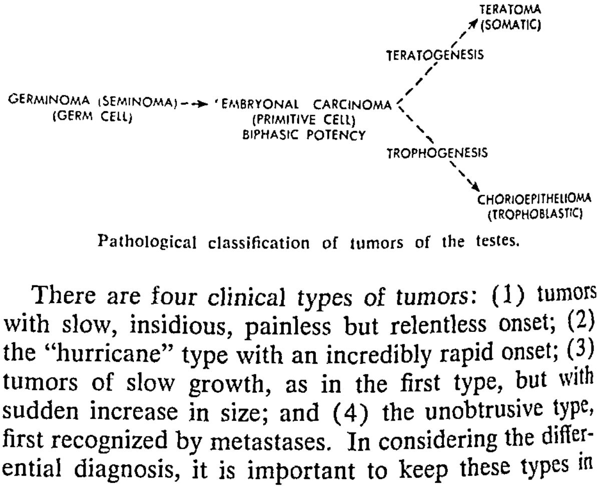
So far as treatment is concerned, the structural patterns may be classified as follows: 1. The seminomas are radiosensitive. 2. The other types are radioresistant, including embryonal carcinomas, teratomas, teratocarcinomas, chorioepitheliomas, and the miscellaneous tumors. Seminoma (germinoma) may be the precursor of embryonal carcinoma, teratocarcinoma, and chorioepithelioma, and may metastasize as these types[1] (see figure).

METASTASES

Tumors of the testes metastasize first and most frequently by the lymphatics but may metastasize by the blood stream. Early metastases by the lymphatics will be unilateral and located in the lumbar lymph nodes situated between the bifurcation of the common iliac arteries and the renal pedicle. The disease is curable by radical resection of these nodes, provided the operative treatment is accomplished before generalized dissemination has occurred. Later in the course of the disease, generalized dissemination to the lungs and other organs takes place by the blood stream and lymphatics.

SYMPTOMS

The initial symptom is almost always a painless swelling of the testis accompanied by a sense of weight in the scrotum. Insignificant trauma may bring the patient's attention to the mass and may often account for the listing of trauma as an etiological factor.



TERATOMA (SOMATIC)
TERATOGENESIS
GERMINOMA (SEMINOMA) (GERM CELL)
EMBRYONAL CARCINOMA (PRIMITIVE CELL) BIPHASIC POTENCY
TROPHOGENESIS
CHORIOEPITHELIOMA (TROPHOBLASTIC)

Pathological classification of tumors of the testes.

There are four clinical types of tumors: (1) tumors with slow, insidious, painless but relentless onset; (2) the "hurricane" type with an incredibly rapid onset; (3) tumors of slow growth, as in the first type, but with sudden increase in size; and (4) the unobtrusive type, first recognized by metastases. In considering the differential diagnosis, it is important to keep these types in mind.

Local tenderness is absent or relatively slight. Loss of weight, cough, pain in the abdomen and back, and gastrointestinal symptoms due to metastases may occur late.

DIAGNOSIS

Early diagnosis is one of the most important factors in the prognosis of tumor of the testis. The differential diagnosis is not difficult. Every mass in the scrotum should be considered malignant until proved otherwise. Bimanual examination is imperative. For painful lesions, general anesthesia may be necessary in order to properly evaluate the condition of the scrotal contents. Epididymitis, thick-walled hydroceles, and hematoceles are the most difficult to differentiate. Hydroceles that have been tapped frequently are very confusing. Careful estimation of the size, consistency, contour, and weight of

Urology Section, Surgical Service, Walter Reed Army Hospital, Washington, D. C.

Read before the Section on Urology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

[1] Friedman, N. B., and Moore, R. A.: Tumors of Testis: Report on 922 Cases, Mil. Surgeon 99:573, 1946.

the testis should be made. On bimanual palpation a malignant tumor of the testis feels heavier than other masses. The clinical recognition is a matter of exclusion. Early diagnosis is lifesaving. The Aschheim-Zondek hormone test offers little in establishing an early diagnosis and may even be confusing because the usually negative response may give a sense of false security and cause loss of valuable time in beginning proper treatment. It is important that the diagnosis be established and treatment be initiated before metastasis takes place. In Lewis'[2] series, metastatic lesions were present in 43% of the patients on admission to the hospital, and metastases developed in 28% soon after admission—a total of 71% of cases with metastases caused by delay in diagnosis and treatment.

ANALYSIS OF CASES

In the six years ending June 30, 1952, 106 patients with testicular tumors were admitted to Walter Reed Army Hospital. These patients ranged in age from 18 to 46 years, with an average age of 27. In 88 cases the initial symptom was painless swelling of the testis. Thirty-two of the patients, however, had pain in the testis sometime prior to surgery. This is of interest, since 22 of the patients were treated initially for epididymitis.

The initial diagnosis in 64 patients (60%) was tumor. An erroneous initial diagnosis was made in 42 patients (40%). The commonest diagnostic errors were epididymitis and orchitis. Careful bimanual examination of the testes would be an aid in differential diagnosis.

The lag between the onset of symptoms to the diagnosis was 7.2 months in the entire series, 7.5 months in patients with metastasis, and 9.0 months in patients with an erroneous first diagnosis. The pathological diagnoses with the percentages of metastases are shown in table 1.

Fifty-one patients (48%) had metastases at the time of the radical lymph node dissection. In 2 patients solitary pulmonary metastases developed following a radical retroperitoneal lymph node dissection in which there was no pathological evidence of extension. Thoracotomy with resection of the involved lobe was carried out, and in nine months follow-up there was no recurrence of the lesion. Twenty-six patients are known to have died, and all had metastases at the time of surgery. The hormone test was performed in 97 patients and was positive in 17 (17.6%). Four of these patients had chorioepithelioma, two choriocarcinoma, eight teratocarcinoma, two embryonal carcinoma, and one seminoma. The history and physical examination are paramount, and treatment should not await the results of the hormone test.

TABLE 1.—*Types of Testicular Tumors Observed and Percentages with Metastases at Walter Reed Army Hospital from July, 1946, to June, 1952*

Type of Tumor	Total No.	No. with Metastases	%
Epidermal cyst..................	1	0	0.0
	39	6	15.4
	34	20	58.8
	13	10	76.9
	12	9	75.0
Chorioepithelioma..............	6	5	83.3
Adult teratoma..................	1	1	100.0

Simple orchiectomy was performed in 12 patients, orchiectomy with radical retroperitoneal lymph node dissection in 93, and removal of the tumor from the testis in 1. Simple orchiectomy was performed in patients with obviously inoperable metastases. There have been no deaths from radical surgery at this hospital.

TREATMENT

The treatment for testicular tumors is radical surgery followed by appropriate irradiation. Orchiectomy, with resection of the spermatic cord, spermatic vessels and retroperitoneal lymph nodes, should be carried out for all malignant tumors of the testis if a cure is anticipated.[3] The incision for the lymph node resection is made from the external inguinal ring to the midaxillary line between the 10th and 11th ribs. It may be continued posteriorly with the risk of entering the thorax. This type of incision provides good exposure to the renal pedicle and diaphragm. Radical surgical treatment with irradiation has given better results than orchiectomy plus irradiation (table 2).

TABLE 2.—*Comparison of Survival Rates of Series of Patients Treated with Irradiation and Orchiectomy or Radical Surgery*

	U. S. Naval Hospital *		Walter Reed Army Hospital †		
Type of Tumor	No. of Patients	% Survived	No. of Patients	% Survived	Difference in Percentage
Seminoma (radiosensitive)	75	59.6	103	81	21.4
Teratocarcinoma embryonal carcinoma (radioresistant)	141	19.1	100	37	17.9
Total................	216	31.7	203	57	25.3

* In this series orchiectomy plus irradiation was the method of treatment.

† In this series radical surgery plus irradiation was the method of treatment.

Although seminomas are more radiosensitive than other types, radiation therapy alone cannot be depended upon to control the tumor spread. Friedman and Moore,[1] in their series of 922 patients, found 319 with seminoma. In a later report, Friedman [4] noted that of the 28 patients with seminoma who had metastases, 11 (39.3%) had metastases of embryonal carcinoma, teratocarcinoma, or some other type. This type of radioresistant metastasis makes surgical excision of the testis, spermatic cord, spermatic vessels, and retroperitoneal lymphatics the treatment of choice. The operation is followed by appropriate irradiation.

Advances in irradiation therapy equipment have been so rapid in recent years that evaluation of results, even by experts, is very difficult. Many powerful and dangerous tools have been discovered and developed. The supervoltage unit and radioactive isotopes may radically change the treatment of malignant tumors. Some physicians believe that the therapeutic application of these elements may become so effective that the use of the scalpel may soon be obsolete in the management of cancer. Methods and equipment rapidly become outmoded, and future treatment is unpredictable, but certain basic factors remain steadfast. It is proverbial that the more

3. Moore, R. A.: Teratoid Tumors of Testes (Ramon Guiteras Lecture), J. Urol. 65:693, 1951.

4. Friedman, N. B.: Comparative Morphogenesis of Extragenital and Gonadal Teratoid Tumors, Cancer 4:265, 1951.

conditions appear to change, the more they remain the same.

The 1,000 kv. radiation unit is in common use, and treatment with this type of apparatus has been standardized. At present the 2,000 kv. supervoltage unit with rotation exposure is considered the safest and most effective type of irradiation.

Preoperative irradiation has no place in the treatment of malignant tumors of the testes. Postoperative irradiation is considered under the following headings: (1) curative, (2) prophylactic, and (3) palliative.

Curative Irradiation.—It is asserted by some authors that seminoma is curable by irradiation alone. There is, however, considerable doubt that such therapy will eradicate deep-seated cancer. If irradiation alone will cure seminoma, there should be no mortality following such treatment.

Prophylactic Irradiation.—All seminomas (radiosensitive tumors) as well as radioresistant tumors that have presented metastatic extension at operation are irradiated postoperatively. Radioresistant tumors that show no metastases at operation are not benefited by irradiation, and such therapy only complicates convalescence.

Palliative Irradiation.—Irradiation is used to relieve pain, delay the spread, and prolong life in patients with hopeless metastases.

Pulmonary invasion has been treated by thoracotomy and resection of the solitary metastasis in four patients. The immediate result in two patients has been encouraging, but insufficient time has elapsed for evaluation of the efficiency of this type of therapy.

Three patients with extensive metastatic spread associated with severe pain were treated by castration and estrogen therapy. The metastases receded, and the pain was relieved. Further study may prove this type of palliative treatment to be useful in prolonging life and, in some cases, contribute to the patient's comfort.

STANDARD OPERATIVE PROCEDURES AT WALTER REED ARMY HOSPITAL FOR TREATMENT OF TESTICULAR TUMORS

Radical orchiectomy is indicated for all malignant tumors of the testis that show no clinical evidence of extension outside the retroperitoneal space. Postoperative treatment includes postoperative irradiation for radiosensitive (seminoma) tumors with or without pathological evidence of extension to the retroperitoneal space. Radioresistant tumors without pathological evidence of extension to the retroperitoneal space are not treated by postoperative irradiation. Postoperative irradiation is used for radioresistant tumors with pathological evidence of extension to the retroperitoneal space.

When extensive metastases are present, treatment includes bilateral orchiectomy, administration of estrogen, and irradiation. In the presence of a solitary metastasis to the lung following radical orchiectomy, thoracotomy with resection of the metastasis and adjacent lung is done and irradiation is applied.

SUMMARY AND CONCLUSIONS

Cancer of the testis is totipotent. Radiosensitive seminomas often metastasize as radioresistant tumors. The important factors in the prognosis of cancer of the testis are as follows: (*a*) structural pattern; (*b*) stage of development at time treatment is begun; and (*c*) type of treatment. The treatment of choice is orchiectomy, resection of the spermatic cord, spermatic vessels, and retroperitoneal lymph nodes, followed, when indicated, by appropriate irradiation therapy.

INDUSTRIAL MEDICAL SERVICE BY PRIVATE PRACTITIONERS

James. P. Hughes, M.D., Cincinnati

Industrial organizations are making increasingly heavy demands on the medical profession for sound guidance on matters of employee health. What is needed, it would seem, is more emphasis on the preventive aspect of medicine and less on the curative aspect. While injuries and some occupational disorders such as contact dermatitis continue to occur with some frequency, it has become unusual for even a large industrial plant to have many. Safety engineering practice has been developed to the point where many employees are actually safer on the job than at home or on the highway. The majority of industrial injuries that do occur are minor and respond quite well to the type of treatment that competent industrial nurses are trained to administer under medical supervision. In few plants does the practice of traumatic surgery require a large part of the time of medical personnel. A growing portion of medical time in the plant is being devoted to other and more fruitful pursuits. These are concerned with the preservation of the health of employees by means of active health education, by the control of environmental hazards, and by periodic health appraisals. Industry is prepared to sponsor these positive health measures.

Totally aside from the desire of some employers to make available to workers these well-tested preventive techniques for their own sake, adequate economic incentive for establishing employee health guidance has now been provided. Preventive medicine in industry is just entering a period that promises to be one of rapid development. An analogy may be drawn to the real beginnings of the industrial safety movement some 40 years ago. With the widespread adoption of state workmen's compensation statutes, the loss of life or limb due to occupational injuries became such a catastrophic financial burden to industry that a solution was forced, and the safety movement was born. When it was demonstrated consistently that pennies spent on accident prevention resulted in dollars saved on compensation payments, progress in safety engineering led to almost un-

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

believable improvement in accident experience in the most hazardous industries. Hospital accident wards are no longer filled with the human carnage of factory accidents.

NEW ECONOMIC PRESSURES

Other economic pressures have now developed. Some have arisen out of new solutions to labor-management conflict, while others have been stimulated by statutory provisions for payments to employed persons temporarily disabled from any cause. These new pressures are (1) the importance of "fringe benefit" provisions in labor contracts; (2) the growing tendency of labor organizations to establish medical programs operated entirely at employer expense; and (3) compulsory state disability compensation laws.

During the recent periods of the application of government controlled wage ceilings, the practice of liberalization of "fringe benefits" by collective bargaining has flourished, providing economic advantages to workers in lieu of actual wage raises. These provisions usually have included pension plans with provision for premature retirement due to permanent disability, hospitalization and surgical insurance, and the payment of at least partial wages during periods of temporary disability from any cause largely, or entirely, financed by the employer. In 1951, the average fringe payments reported by a representative cross-section of American industrial firms amounted to 18.7% of the payroll, or $644 per year per employee, paid in addition to actual wages.[1] The sound administration of these benefit plans, distributing in the aggregate some 1.5 billion dollars yearly and largely related to the health of employees, requires competent medical advice.

Labor unions have become health conscious. Several large unions have established medical programs for their members, chiefly in the needle trades, in some service trades, and in the automobile industry. These health plans are administered by the unions, and usually are financed completely by employers. The plans tend to include complete medical care, often for the entire family of the union member. When the development of employer-sponsored industrial health programs has lagged, either for lack of employer interest, or because an industry may be made up of numerous small employers, such as the garment manufacturers, then the union plans have flourished. While most employer programs are limited to the care of occupational disability and to the provision of preventive measures, with insistence that the other aspects of medical care remain in the field of private medicine, the union programs are more likely to control complete medical service. But where the employer has hesitated to provide reasonable on-the-job health guidance, he sometimes has found himself paying for around-the-clock medical care for the workman and his entire family. Companies in growing numbers are seeking assistance in setting up medical programs of their own choosing.

The third major economic pressure arises out of the compulsory disability benefits laws now in effect in 4 states, with similar bills under consideration in at least 15 other state legislatures. In two of the states having such laws, New York and New Jersey, a considerable portion of the cost of state payments to persons absent from work because of illness or injury is borne by employers. In addition to this direct monetary stimulus, an additional incentive for employers to increase their participation in health maintenance measures and health education may be expected to result from analysis of the statistical records accumulated under these plans.[2]

Even the employer who may not yet have felt the impact of these economic forces is being reached by other arguments for improved health facilitites in industry. Management is besieged with data on the benefits to be derived from a sound medical program. Much of this proselyting material is now coming from sources close to industry—from the National Association of Manufacturers,[3] from the American Management Association, and from other trade associations and professional business groups. The effectiveness of the industrial health program in reducing sickness absenteeism and labor turnover, in cutting compensation costs, and in improving employee morale is being widely discussed. A note of hopefulness is being sounded that the benefits of a company health program may be felt in the improvement of community health. For all of these reasons, humanitarian and economic, American industry is reaching out to medicine for help.

ROLE OF THE PHYSICIAN

How are we prepared to render such help? Who will provide the necessary guidance in matters of industrial health? Even nominal medical service to industry cannot be provided by the efforts of those who choose to practice industrial medicine exclusively. The great bulk of these services will continue to be rendered by the private practitioner of medicine. Whatever benefits of preventive medicine as applied to industry are to be enjoyed by the nation's workers will reach them only through the interest of private practitioners who have equipped themselves for effective service in industry.

The physician who recognizes that his best effort cannot be made from outside the plant and therefore undertakes to extend his activities to the industrial setting is likely to find himself bewildered by the complexities of organization and the seemingly conflicting aims that characterize the operations of many companies. On the one hand, the production departments, as well as the maintenance and sales departments, will be striving for constantly improved records of achievement and may be doing so with little recognition of human emotional and physical limitations. At the same time, the employee services department, including the medical section, should be pulling just as hard for increased recognition of factors of safe working conditions and the importance of proper job placement in keeping with the true capabilities of employees. Where research and development teams may be bringing forth complex and perhaps highly dangerous new compounds, a health group should be keeping up

adequate toxicologic data on these materials. As the physician enters into this apparent conflict of dynamic forces, he soon learns that his greatest effectiveness in maintaining and improving the health of the workmen comes only through sound working relationships with certain groups in the plant. These relationships, in the order of importance, are with the employees, with professional colleagues, and with management.

PATIENT-PHYSICIAN RELATIONSHIP

The physician in industry has the same moral, ethical, and legal obligation to the employees who voluntarily seeks his counsel that he has to patients in the more familiar surroundings of his own practice, despite the fact that usually he is dealing with the private patients of a colleague. It is imperative that this ethical and legal principle of behavior be adhered to by the industrial physician and that the significance of it be conveyed to employee and to management alike. The fact that personal medical records are kept in the medical department or the office of the physician, are held in strict confidence, and are not subject to review by management is a useful measure in establishing the spirit of trust in the physician that must exist in the plant. It is to be expected that, when the physician first appears at the plant, he may encounter an attitude of at least cautious appraisal, if not of suspicion. The physician initially may be considered to be simply a servant of management—by the employees, sometimes by his professional colleagues, and, occasionally, even by management itself. When the physician has demonstrated the fact that his first concern is for the welfare of the patient, it is gratifying to observe the rather prompt change in attitude from one of partial mistrust to one of complete acceptance and confidence.

Misunderstandings that arise with respect to the confidential nature of plant medical records may be dispelled by consideration of the basic principles of what constitutes privileged information. In general, the patient-physician relationship is established when a person voluntary presents himself to a physician for diagnosis leading to treatment. Any information given the physician by the patient under these circumstances is privileged, regardless of whether the consultation is held in the medical department of an industrial plant or in the private office of the physician. The results of any diagnostic studies conducted as part of such consultation must be held confidential. These precepts apply in the usual types of employee visits to the plant medical department for the emergency care of nonoccupational conditions and particularly in cases of voluntary periodic health appraisals. A somewhat different situation exists when an employee presents himself to a physician designated by employer or insurance carrier for the treatment of a work-incurred injury or illness. In these cases, no confidential historical information need be offered by the patient. The fact of his appearance before the approved physician is taken as consent for the dissemination of information concerning the injury or illness to the proper compensation agency. The established channel through which this information flows is usually the personnel department or the employee welfare section of the plant.

Other circumstances under which the patient-physician relationship is not established are those of the preplacement physical examination of job applicants. The applicant need render no information as the basis for treatment, since no treatment is to be given. The results of the physical examination therefore may be made known to the employment office that has referred the person for appraisal. When the preplacement physica examination is carried out in a plant medical departmen or in his private office by a physician responsible for th health maintenance of a group of employees, the actua details of the examination should be held in confidenc by him; only such information should be given to th employer as will be necessary for proper job placemen This is usually accomplished by the use of a system classification in which the suitability of the applicant f certain types of work is indicated without actual dia nostic information being revealed. Obviously, the ph sical requirements of the jobs in question must be know to the physician if he is to reach an intelligent and realist decision on job placement based on the physical abiliti of the applicant.

The wisdom of safeguarding medical informati acquired in the course of the examination of applica and employees, even when such information is legally regarded as privileged, is apparent. The physici who holds the true interests of the examined person be preeminent under all circumstances is making most effective approach to his medical duties in the pla

PROFESSIONAL RELATIONSHIPS

In the past, professional relations between the ind trial physician and the private practitioner have b disturbed by the attitude on the one hand that the priv practitioner has not, by training or experience, quali himself to deal with occupational diseases and on other hand, that the industrial physician, totally divor from private practice and only secondarily intereste therapeutic medicine, is not to be dealt with as an e and respected colleague. Happily this rather awkw situation is changing. It is of significance that the Am can Academy of General Practice in a recent poll fo that about 93% of its members have some direct o direct responsibility for medical service in cases industrial origin. The private practitioner who is ca on to render medical advice to an industry even o sionally, usually becomes quite sympathetic toward nature of the activities of the full-time or the part- industrial physician. Kehoe[4] has suggested further s tion in this way: "There must be concerted action o part of physicians in and out of industry, to see tha health and lives of industrial workers are safe-gua in the most effective manner. This concerted action not be achieved by mutual formal exchanges of pr sional courtesy, but by the direct and frank collabor of men who know their way about in their respe fields of work."

The role of the nurse in industry differs some from that of the hospital nurse and the public h nurse. Industrial nursing is rarely bedside nursing t large degree. While the day's work may be occupied with minor medical and surgical treatments, the competent nurse in industry also has been imbued with the preventive idea, for the purposes of maintaining health and of assisting in the control of disease and accidental injury. In the industrial plant she is not under the vigilant eye of a hospital floor supervisor, and she savors this relative freedom. Nonetheless, she requires and expects the interested direction of a physician. She can participate in rendering personal medical services involving diagnosis and definition of treatment only when acting under direct medical supervision, or under indirect supervision such as that provided by formal standing orders. The nurse usually is the first to recognize her professional, ethical, and legal limitations in these matters. The physician who serves industry on even a part-time basis must provide the sound and continuing type of medical supervision that all well-trained nurses expect.

---

[4] Kehoe, R. A.: Place of Individual Physician in Industrial Health, Cincinnati J. Med. 25:49, 1944.

An industrial hygiene engineer may be employed in the larger plant. The physician is very likely to have some contact with a person of this background, who either is on the staff of the medical department or comes as a technical consultant. The function of the industrial hygiene engineer may be defined as "the study and control of environmental factors affecting the health and well-being of industrial workers." [5] This is a large order, and to a very considerable degree we are all engaged in this pursuit. The particular interest of the engineer is in the description of the physical and chemical nature of the industrial environment and the design of facilities that will result in the elimination of undesirable characteristics. His skills may include techniques for sampling the atmosphere, for analyzing its components, and perhaps for substituting safe materials for dangerous ones. His effectiveness is greatest when he is given the opportunity of reviewing proposed plant operations, from a health and safety standpoint, while these operations are in the planning stage. He is an invaluable member of the industrial health group. Without entering into controversy relative to the proper place for the industrial hygiene engineer in the organizational plan of the company, it may be said that his activities perfectly complement those of the physician trained in occupational medicine and may be essential to those of the physician whose interests in industrial health are more casual.

RELATIONSHIPS WITH EMPLOYERS

The physician who has a clear concept of the nature of his ethical responsibilities to the employees, and communicates this information to management at the appropriate time, should have no difficulty in dealing with industrial personnel on medical matters. Constant education of supervisory personnel is necessary, because it is at this level that one often encounters a fierce, fanatical, and sometimes rather blind loyalty to what erroneously may be considered the best interests of the company, even to the detriment of the employee. A patient but inflexible attitude of fairness by the physician is required in pointing out that the true interests of the employer can only be served by careful consideration of what is best for the employee.

An example may serve to illustrate this point. The management of a plant may be so proud of a good safety record that it becomes a thing to be zealously guarded. This is true of the safety department to an even greater degree. According to the rules of scorekeeping in such matters, only injuries resulting in actual disability affect the safety record. One of the chief determinants of disability is loss of time from work. When an injury occurs, for example, a low back strain, the safety department may temporarily lose sight of the best medical interests of the injured employee. There is frantic effort to protect its recognized standard of efficiency, the safety record. In some plants it may be suggested that a newly injured man, on crutches or in a heavy cast, be delivered to the clockhouse for the purpose of simply punching his time card, establishing for the sake of the record his ability to work and thus avoiding that symbol of safety failure, a lost-time accident. This is not according to Hoyle, but I have heard that it has been done. The duty of the physician in these cases is quite clear. While early return to work has become an accepted principle of rehabilitation of the injured, decisions based on considerations other than the welfare of the patient cannot be countenanced.

When a person is to be returned to work after injury or prolonged illness, he cannot be expected to have the same level of physical proficiency for his tasks that he had before the onset of his disability. This is particularly true where the job may be one requiring considerable exertion or skill of coordinated movements. Common sense dictates a gradual return to full duties. The foreman of a work crew is often restricted by management policy, perhaps abetted or even dictated by terms of a labor contract, to a specified number of men to perform a certain job. While he may easily absorb into a small group one or two workmen whose physical activities have been restricted on medical recommendation, there is a limit beyond which he cannot go if the day's work is to get done. He may then become unwilling to accept men who can perform only limited duties. At this point the physician, who has already convinced the safety man that a certain injured man requires a period of recuperation off the job, now has a new problem. He may now consider the man ready to begin to resume his work activities on a gradually increasing scale, only to find that the foreman does not want the man back until he is completely fit. Patience and careful explanation again will be required.

The physician who is new in industrial medicine finds that his decisions, if they are to be respected as well as observed, must be based upon certain practical considerations in addition to exclusively medical ones. The physician may be accustomed to making pronouncements on health matters without explanation, but if he wishes to lay the foundations of a sound working relationship in the plant, he will avoid in his actions the unnecessarily arbitrary manner that may be accepted but is always resented.

Kettering Laboratory, University of Cincinnati College of Medicine.

IMPORTANCE OF STANDARDIZATION OF NURSING HOMES

Thomas P. Murdock, M.D., Meriden, Conn.

The subjects of long duration illness and the care of the aged are close to my heart and are conditions that I have been interested in for many years. Life expectancy in the United States has increased and, I am sure, will continue to increase for many years to come until this nation enters its period of deterioration, which must come to all nations. Then we will get a reversal of this trend. A child born at the turn of the century had a life expectancy of about 49 years.[1] A child born today has a life expectancy of about 69 years. One does not have to be a great prophet to predict that, before long, we will pass the biblical expectancy of three score and ten.

There are several reasons for this increase, and among these we think of the great advances in public health and sanitation. A good example of this is typhoid, a disease rarely seen now. Many young doctors and nurses probably have never seen a case. The great advances that have been made in intracranial, thyroid, thoracic, gastrointestinal, and genitourinary tract surgery have contributed largely to this increase. We may expect continued advancement and improvements in these fields. The diabetic at the turn of the century was a very pathetic sight. A tentative diagnosis of his condition could be made on physical appearance alone. Then in 1921 came insulin, the work of the immortal Banting and his associate, Best. Now the diabetic will usually outlive his doctor. In 1926 came liver extract for the patient with pernicious anemia. Prior to that time, many patients died from this disease. In the past few years vitamin B_{12} has been added to our armamentarium for this disease. The patient with pernicious anemia now frequently lives to old age. The year 1935 brought the sulfonamides for use against acute infections. The early 1940's brought the various antibiotics to supplement the sulfonamides for acute infections and for other purposes. It is now unusual for patients to die from the known acute infections, and more persons live on to old age.

The forgotten men in medicine are the general practitioners and the pediatricians. The research worker who has discovered the cause of, or treatment for, a specific disease is duly recognized, and his name is immortalized in medical history. The general practitioner and pediatrician who have, more frequently than any others, brought these discoveries to the people are seldom thought of. I have in mind particularly their noble work in immunization against diphtheria, scarlet fever, and pertussis. These diseases took many children's lives. I have in mind also the work in the prevention of nutritional deficiencies and infectious diarrheas in children. All of this work has contributed largely to increasing life expectancy. In other words, the immunizations against the diseases of childhood and the prevention of nutritional deficiencies and infectious diarrheas have contributed largely to our new problems of the aging.

CHANGING CONDITIONS

I think it can be said that the philosophy of the American people began to change in the late 1920's or early 1930's. Out of this change, of course, came some good things. Out of it also came some unfortunate conditions. The good, of course, we think of at once: an increased standard of living with better housing, improvement in sanitation, and improvement in working conditions. At the turn of the century, men not infrequently went to their work, during some seasons, in the dark and returned from their work in the dark, never having been in the sunlight. God, or men with social consciences, never intended this.

With the improvement there also occurred some unfortunate conditions. One has only to reflect a little to detect an unwillingness on the part of younger persons to care at home for the aged, and they are sent to nursing homes. During World War II, there was a great shortage of manpower. Married women were called into industry, on the basis of patriotism, but, as time went on, they continued to work. Time has proved that this continuance in many instances was actually for the purpose of buying more frills than could otherwise be provided. Of course, something or somebody had to suffer. It is difficult to work and care for a home. The aged have suffered, and children are beginning to suffer. The term "baby sitter" that came into being about this time now has a very broad meaning and is very widely used. Time alone will tell us whether the improvements that we all accept as good are outweighed by the destruction of a moral philosphy that was standard and accepted before this change. I am old-fashioned enough to believe that the latter is true and that we may now be looking at the beginning of our national deterioration.

The general hospitals in this country have increased in numbers and capacity beyond the expectation of most men. In 1909 there were 4,309 [2] registered hospitals. In 1952 there were 6,665 registered hospitals, with a bed capacity of 1,541,615. The Hill-Burton act, a one-time federal grant for hospital construction, has aided in this increase. Despite this, there is a shortage of hospital beds. It is estimated that there were 3,910,000 births in the United States in 1952. Of this number, 3,170,495 babies were delivered in hospitals. In some states 95% or more were delivered in hospitals. The cost of hospital care has increased a great deal. This was to be expected with the changing philosophy and with a large part of the increase being due to the increased costs of materials and labor.

NEED FOR NURSING HOMES

At this point one asks the question: Are there great numbers of persons with long-duration and probably incurable illnesses in general hospitals who could be cared

---

Read at the meeting of the American Association of Nursing Homes, Minneapolis, Sept. 1, 1953.

[1] Dickinson, F.: Mortality Trends in the United States: 1900-1949, Bureau of Medical Economic Research, bulletin 92, Chicago, American Medical Association, 1952.

[2] Hospital Service in the United States, report of the Council on Medical Education and Hospitals of the American Medical Association, J. A. M. A. 152: 145 (May 9) 1953.

for as well, if not better, in nursing homes? I think there are. The question, however, is in dispute. Bluestone[3] of Montefiore Hospital feels that a large number of those in nursing homes belong in general hospitals. He also feels that the minority belong in nursing homes or in their own homes. Blue Cross,[4] Blue Shield, and old line insurance companies now provide coverage against catastrophic illnesses for a very large segment of the population. Approximately 90 million persons are covered against the cost of hospital care, 72 million against surgical costs, and 32 million against medical costs. This, I believe, is and should be the answer to those who believe in the federalization of medical care—the first step in complete socialization.

At the national level, the question of chronic illness is being studied intensively on two fronts. A suburban study is being carried on in Hunterdon County, New Jersey, and an urban study in the Baltimore area. Included in the latter study is the nursing home question. Four other states are now carrying on studies of nursing homes. The question of rehabilitation, so long ignored in this country, and now spearheaded by Dr. Howard Rusk, is bringing valuable and encouraging information to the front. Patients, particularly young patients, previously accepted as being totally disabled, are again taking their useful places in society. Industry is attempting to find places for partially disabled men and women. The National Foundation for Infantile Paralysis, as it continued its intensive studies of the viruses of this crippling disease and the production of a vaccine, has carried on a splendid rehabilitation program with grants and fellowships toward improved methods of rehabilitation, and at the same time has encouraged direct application of known methods for the relief of these unfortunate persons.

What does all this add up to? The overloading and overburdening of the general hospitals, the increased cost of hospitalization, the increase in life expectancy, the large numbers of persons covered by prepaid hospital and medical plans, and the undoubted increase in the number of persons suffering from long-duration illness all indicate that from this time on the nursing homes will take their rightful places in the sun. It is stated that there are 14,000 nursing homes[5] in the United States. Dr. Frank Dickinson,[1] of the Bureau of Medical Economic Research of the American Medical Association, states that there are about 11 million persons over 65 years of age in this country. He also estimates that in 1970 there will be between 15 and 18 million in this age bracket. He lists the three important causes of death in those over 65 as heart disease, cancer, and vascular disease. These statistics sustain the medical opinion that persons in the older age bracket are particularly subject to long-duration illness. They also indicate the necessity now for an increase in bed capacity and preparations for the future. If this increase in bed capacity in nursing homes is accomplished, it will serve a threefold purpose. The general hospitals will have more beds available for acutely ill patients, the general cost of hospital care will be reduced, and the care of the patient with long-duration illness will be improved and specialized in nursing homes.

CRITERIA FOR NURSING HOMES

Standardization and accreditation become increasingly important as we progress in our methods for the care of the sick. The Joint Commission on Accreditation of General Hospitals has been in operation since 1952. The Council on Medical Education and Hospitals accredits hospitals for the training of interns. The Committee on Accreditation of Nursing Schools has been in operation for about a year. These are individual or joint efforts of the American Hospital Association, the National League of Nursing, the American College of Surgeons, the American College of Physicians, and the American Medical Association. I think it is fair to say that there are good and poor nursing homes in this country. I feel that this is the place where your organization must step in to improve conditions. The time has come, I believe, for the standardization of nursing homes. This should be done by your organization. It must be done, in my opinion, cautiously and carefully. It should be done on a basis of pattern direction and should be a voluntary approach. By this I mean general guidance and advice to state or member organizations as to standards and requirements.

At present the public health laws and fire laws of the various states make certain specific requirements. This is as it should be, and they must be religiously enforced. Obviously older persons or disabled persons need greater protection than the young and well. The progressive cities or states are those that have adequate public health laws and fire laws. The Council on Medical Education and Hospitals of the American Medical Association now registers some nursing homes. Of course, it would be physically impossible to cover all of the 14,000 nursing homes in the United States. The Council can, and I am sure will, aid your organization in its direction of patterns. Specifically, several recommendations can be made as to medical care in nursing homes. Where possible, these homes can be annexed to the general hospital. If this is not possible, an affiliation with a general hospital may be accomplished. It is of benefit to the general hospital to know that a suitable affiliation exists where their patients with long-duration illness will be adequately cared for. I would urge that, wherever possible, the medical care be provided on a voluntary basis. In the larger homes, by which I mean those of 100 to 200 beds, I would recommend that a regular staff be appointed. If the home is attached to a general hospital, the staff can be provided by the general hospital. If not, the county or city medical society will aid in the selection. In smaller hospitals, the same procedure will apply, or the patient may have his own physician. Wherever possible, the free choice of physicians should apply. I believe that all patients should have preadmission chest roentgenograms. These should be considered a must. Obviously, the patient with pulmonary tuberculosis belongs in a tuberculosis hospital and not in a nursing home. In general, and I say this from wide experience, the mode of living of the older patient should not be changed too much. One should not be

5. Waterman, T. L.: Nursing Homes—Are They Homes? Is There Nursing? Am. J. Pub. Health 43: 307 (March) 1953.

ultrascientific at the price of great discomfort to the patient. Keeping him comfortable and happy is more important than overindulgence in academic curiosity. I think it necessary that a physical examination of the older patient be done twice yearly and more frequently if some acute conditions develop. I doubt the wisdom of exhaustive laboratory studies. If these are required, the patient can be transferred to a general hospital for immediate and intensive care. Some of the simpler procedures, such as blood cell counts, urinalyses, and blood sugar determinations can be done. These could be done very well by a technician. In the case of smaller homes, one technician could well service several. In the case of the very small homes, these might well be covered by the physician, or a reputable commercial laboratory.

I know that in any effort toward the elevation of standards you will have the cooperation of the medical profession. The medical profession recognizes the importance of nursing homes and is anxious for the improvement of standards. We must always bear in mind that the nursing home is and should be operated for the kindly, gentle care of these old persons who find themselves in the late period of their lives without any place else to go, who are entitled to good care, and who do not need overly scientific study. Of all of the services required for the aged and those suffering from long-duration illness, I would place nursing first. I say this with a full appreciation of the other allied services necessary. It is now agreed by all that there is a great shortage of nurses in this country. There is no single cause for this shortage. The causes are multiple and include the low birth rate in the early 1930's with fewer young women now of working age, and the competition of industry, clerical work, teaching, and other fields open to young women. Finally, higher wages are obtainable in other fields of endeavors after a much shorter period of training or no training at all. The shortage presents itself in bedside nurses and teachers. The study now under way by the Committee on Accreditation of Nursing Schools brings this out clearly. The Committee of the American Medical Association for the Study of the Nursing Shortage made the following strong recommendations in its report in 1948: (1) that nurses be made up of three groups: (*a*) 15% collegiate nurses (these women to act as teachers in nursing schools), (*b*) 25% hospital-trained nurses, and (*c*) 60% trained practical nurses; (2) that the courses of the hospital-trained nurses be reduced to two years; and (3) that provision be made and credits allowed, in selected cases, for advancement from one group to another. The committee strongly reaffirmed its position this year. I think it can safely be said that for many years there will be a shortage of nurses if we pursue the old methods of training nurses. The recommendations of the American Medical Association's committee are sound, and if they are followed, I am sure that the shortage will be corrected.

I bring up the question of shortage of nurses and the recommendation of the American Medical Association committee because I believe that nursing homes have suffered and will continue to suffer from this shortage as much or more than the general hospitals. If there is a place for the team concept of nursing, and I believe there is, it is in the nursing home for the care of the aged and those with long-duration illness. I think of the collegiate nurse or the hospital-trained nurse at the top. Depending on the size of the home, I think of the hospital-trained nurses or trained practical nurses in the bracket below. In still another bracket, I think of personnel trained on the job. With this team, the patients will be given good and kindly treatment and care. Regarding the qualifications of the nurse, and particularly the nurse in nursing homes, I should like to paraphrase a statement made for another purpose by Miss Jane Hoey[6] of the Social Security board: The nurse should have (1) a sincere belief in the divine origin of man, (2) a sincere belief in the divine destiny of man, and (3) recognition of the God-like quality common to all men. The nurse with these basic qualifications will be a credit to her profession, and those under her care will be assured of good and kindly care. Of course, adequate theoretical and practical training must be added to these basic requirements.

I have tried to outline for you my evaluation of the present nursing home, its future, and the very high place it has in the healing arts. You are caring for a group of persons in the evening of their day, with the shades drawn, and darkness soon to come. They must be treated kindly, gently, and well. To accomplish this, you must keep your standards high. In this effort, I can assure you of the generous cooperation of the American Medical Association.

CLINICAL NOTES

FATAL HEMOLYTIC TRANSFUSION REACTION CAUSED BY SENSITIZATION TO A NEW BLOOD FACTOR U

REPORT OF A CASE

A. S. Wiener, M.D
L. J. Unger, M.D.
and
E. B. Gordon, Brooklyn

The purpose of this article is to describe a blood factor apparently not encountered previously. A case is reported in which sensitization to the new blood factor caused a fatal hemolytic reaction.

REPORT OF CASE

A Negroid woman, aged 35, was admitted to a hospital in Manhattan with the diagnosis of a bleeding peptic ulcer. According to the information received, the patient had been pregnant three times but had only one living child. On admission a blood count showed severe anemia, 4 gm. of hemoglobin per 100 cc., 1,280,000 red blood cells, and 29,000 white blood cells, with 73% neutrophils, 6% metamyelocytes, and 20% lymphocytes. A blood transfusion was attempted but discontinued after 100 cc. had been administered, because of a reaction consisting of chills and fever. A week later a blood count showed persistence of the anemia, and another

---

From the Serological Laboratory of the Office of the Chief Medical Examiner of New York City and the Blood and Plasma Bank, University Hospital (New York University-Bellevue Medical Center), New York.

blood transfusion was carried out. The intern who administered the blood and who performed the cross-matching test was called back to the patient's bedside because she had gone into shock during the transfusion. The transfusion was discontinued, but all efforts to revive the patient were of no avail, and she died shortly thereafter. We were then asked to investigate the bloods, in order to determine the cause of the transfusion reaction.

TABLE 1.—*Results of Grouping Tests for Patient and Donors*

Source of Blood	A-B-O Group	M-N Type	Rh-Hr Type	Kell Type
Patient	B	MN	$\mathfrak{R}h_1rh$	kk
1st donor	B	MN	rh	kk
2nd donor	B	MN	rh	kk

The bloods of both donors belonged to group B MN rh kk (table 1), while the blood of the patient belonged to group B MN $\mathfrak{R}h_1rh$ kk. The patient had been given Rh-negative blood, because her blood had been erroneously typed as Rh negative. Actually, her blood contained an Rh_0 variant as indicated by the symbol $\mathfrak{R}h_1$, and this accounted for the error in typing. This, of course, had no bearing on the hemolytic reaction.

TABLE 2.—*Titration*[*] *of Abnormal Isoantibody (Anti-***U***) in Patient's Serum*

Temperature of Tests	Test Cells (All Group O or B)	Dilution of Serum								
		Undiluted	1:10	1:20	1:40	1:80	1:160	1:320	1:640	1:1,280
37 C	1st donor	+++	++±	++±	++	+±	+	tr.[†]	—	—
	2nd donor	+++	++±	++	++	++	++	+±	tr.[†]	—
	Patient	—	—	—						
5 C	1st donor	+++	++±	++	+	—	—			
	2nd donor	+++	++	+±	tr.[†]	—	—			
	Patient	—	—	—						

[*] Titrations were carried out in the usual way by the tube agglutination method in a saline medium. In a series of tubes one drop of the appropriate serum dilution was mixed with one drop of a 2% suspension of the indicated red cells. After incubation at the indicated temperature for two hours, the tubes were gently shaken and the reactions read. The strength of the clumping is indicated by the number of pluses, +++ being the strongest reaction possible, namely, one large clump of cells.

[†] At these dilutions faint clumping was observed.

Repetition of the cross-matching test showed that the patient's serum contained an abnormal antibody that strongly agglutinated the cells of both of the two donors. The antibody was of high titer and avidity, so that clumping occurred promptly when the matching tests were carried out, even on the slide with saline-suspended cells.

As shown in table 2, the titer of the antibody at body temperature was approximately 400 units, while the titer at refrigerator temperature was only 40 units. Thus, the antibody had the property of an immune isoantibody, in contradistinction to naturally occurring antibodies such as anti-A, anti-B, and anti-P. The antibody was active by the ordinary agglutination method in saline medium. Treatment of the cells by ficin had no noticeable effect on the strength of the reaction, so that the blood factor involved was evidently not affected by proteolytic enzymes. Tests on a short series of blood specimens showed them all to be incompatible with the patient's serum, so that the factor in question had a high frequency in the population and was apparently not related to any known blood factor. For example, anti-k (anti-Cellano) was immediately excluded, since the patient herself was Kell negative.

It was then decided to test a large series of persons in order to find persons lacking the factor, which was designated **U**. Since a satisfactory symbol could not be devised from the patient's name, the letter **U** was selected to avoid confusion with symbols for previously described blood factors and to indicate the almost universal distribution of the new blood factor. Since the patient herself was Negroid, it was anticipated that such persons would be more apt to occur among Negroids than among Caucasoids, so that both Negroids and Caucasoids were included in the study. To economize use of the serum, of which only a few cubic centimeters had been obtained post mortem, it was used in a 1:20 dilution for the tests. Moreover, after the tests were read, the serum was recovered and used again until it no longer gave satisfactory reactions. In this way we carried out tests on 690 Caucasoids and 425 Negroids. As anticipated, while no negative reactions were obtained in the series of Caucasoids, four negatively reacting persons were encountered among the Negroids, not counting the patient herself.

The blood groups of the five persons thus far encountered with blood lacking the factor **U** are given in table 4. Only persons with group O and group B blood were included, since the patient herself belonged to group B. It is evident that the blood factor **U** is not related to the A-B-O, M-N, Rh-Hr, or K-k systems. Moreover, the distribution is such as to exclude its relationship to any other blood factor described to date.

TABLE 3.—*Results of Tests for Factor* **U** *on a Random Series of Blood Specimens from Negroids and Caucasoids*

Source of Blood Specimens	No. of Persons Tested [*]	Results of Tests	
		No. Positive	No. Negative
Negroids	425	421	4
Caucasoids	690	690	0

[*] Only group O and group B persons were tested, all of whom were residents of New York City.

TABLE 4.—*Blood Groups of Persons*[*] *with Blood Lacking Factor* **U**

	A-B-O Group	M-N Type	Rh-Hr Type	Kell Type
Patient	B	MN	$\mathfrak{R}h_1rh$	kk
1	O	N	Rh_1rh	kk
2	B	N	Rh_0	...
3	O	MN	$\mathfrak{R}h_0$	...
4	B	N	Rh_0	kk

[*] Listed as numbers 1 through 4 in this table, these persons are the same as those referred to in table 3.

COMMENT

In the past month our attention has been called to two other fatal hemolytic reactions in addition to the case described here. One was caused by sensitization to the

Kell factor and the other by sensitization to the hr′ factor. It is evident that blood grouping at the present time is a high specialized field, so that these delicate tests must be carried out only by specially trained persons, if fatal hemolytic reactions are to be avoided. Certainly, the practice of delegating performance of grouping and cross-matching tests to interns with only a very incidental interest in the subject and very little training is to be condemned. In large hospitals there should be no problem in setting up an adequate blood grouping department, while in smaller hospitals use could be made of a central blood grouping laboratory. The medicolegal responsibility of individuals and hospitals concerned with blood transfusion has been the subject of a recent report.[1]

SUMMARY

A hemolytic transfusion reaction caused by sensitization to a new blood factor U is described. The blood factor U was found to be present in every one of 690 Caucasoids tested and in 421 of 425 Negroids tested.

LEUKOPENIA FOLLOWING FUMAGILLIN TREATMENT FOR AMEBIASIS

REPORT OF A CASE

Edward C. Malewitz, M.D., Houston, Texas

Fumagillin, a new amebacide that is produced from a strain of Aspergillus fumigatus, has been claimed [1] not to produce toxic effects on parenchymatous organs including the blood and blood-forming tissues. The occurrence of moderate leukopenia following use of this drug is therefore reported.

REPORT OF CASE

The patient was a 40-year-old white engineer who had lived in various parts of South America for about 15 years. He contracted amebiasis in Venezuela in 1940 and received intermittent treatment thereafter. A random stool examination on Sept. 17, 1952, did not reveal cysts. On Aug. 3, 1953, a specimen obtained via a sigmoidoscope was examined because of mild diarrhea and tenesmus that had started several days earlier. The presence of cysts of Escherichia histolytica was confirmed by iron-hematoxylin stain. He was given 40 mg. of fumagillin daily for 14 days. On the last day of treatment he noted headache and recurrence of mild diarrhea. On Sept. 18, 1953, a stool specimen was reported as negative for cysts. The following week he was seen because of mild transient throat discomfort, which he had felt for the previous two weeks but had not thought sufficiently important to mention. In addition, he stated that the skin of his palmar and plantar surfaces had been completely desquamated. Examination revealed pink new skin on the plantar and palmar surfaces. His temperature was 98.6 F. His pharynx was diffusely injected, but no ulcers or exudate were seen. There was no adenopathy. The remainder of the examination revealed no abnormalities.

A direct smear from the pharynx showed no leukocytes with Wright's stain. Blood studies made on Sept. 24 revealed 13.6 gm. of hemoglobin per 100 cc., an erythrocyte count of 4,900,000; and 3,500 leukocytes per cubic millimeter, with 52% neutrophils, 39% lymphocytes, 4% eosinophils, and 5% monocytes. A blood cell count prior to the amebacide treatment was normal. A repeat blood cell count on Oct. 2 showed the leukocyte count to be 3,300, with 71% neutrophils, of which 58% were segmented and 13% stab forms, 10% lymphocytes, 3% eosinophils, 14% monocytes, and 2% atypical young forms. Toxic granulations were noted. The hemoglobin level was 13.0 gm., with 4,580,000 erythrocytes. Bone marrow and peripheral blood studies by Dr. Charles Spurr on Oct. 8 showed an almost completely normal picture with slight myeloid hyperactivity in the bone marrow but no abnormal cells in the marrow or peripheral blood. The appearance of both was consistent with toxic leukopenia in the recovery phase. On Oct. 20 the leukocyte count was 5,100, almost the same as before treatment.

COMMENT

Except for the headache and throat discomfort previously mentioned, the patient felt well. At no time was there any fever, adenopathy, or other symptoms suggestive of a leukopenia-producing type of infection. No drugs other than the fumagillin and vitamins were taken. There was a history of fungus infection of the hands and feet that might account for the desquamation, but no active fungus disease was detected. No exposure to toxic chemicals or radioactive materials was discovered.

The dosage used was well below the maximum recommended at that time, and in over 300 cases already reported most of the treatment schedules were as high or higher without untoward effects. Recently a slightly lower starting level was advised, with gradual increases, depending on clinical tolerance. In all cases, the toxic effects were primarily related to gastrointestinal irritation.

No data regarding absorption are available, but it appears that at therapeutic levels very little of the drug is absorbed. No effect on the normal flora of the intestine has been produced. In monkeys, Anderson and coworkers [1a] found the leukocytes either slightly increased or decreased, but no abnormally low decrease was recorded. Also, there was oftener an increase in hemoglobin and erythrocytes than a decrease. No effect on prothrombin activity was found, but there was some retention of sulfobromophthalein (Bromsulphalein), which was permanent in one animal. High dosage in dogs and cats leads to a depression of prothrombin activity and, in dogs, renal tubular degeneration and leukopenia.

It would seem, therefore, that fumagillin is capable of causing parenchymatous degeneration and depression of bone marrow activity when given in high enough dosage. At levels of 60 mg. per day or less in man, there is usually little absorption or very little toxic reaction to this compound. In the case described, the patient may have absorbed unusual quantities of, or have been particularly sensitive to, the drug with resultant depression of bone marrow activity. For these reasons, higher dosage than that recommended or repeated courses of this amebacide are not advisable unless frequent studies, especially for detection of liver and bone marrow toxicity, are made.

SUMMARY

A case of mild leukopenia following treatment of amebiasis with fumagillin is reported. Since this is a rare occurrence, further trial of this apparently well-tolerated and effective drug is justified, but sensitivity should be suspected and proper precautions taken.

COUNCIL ON PHARMACY AND CHEMISTRY

The following abstract of recent nomenclature decisions of the Council is authorized for publication.

R. T. Stormont, M.D., *Secretary.*

NEW GENERIC AND BRAND NAMES RECOGNIZED BY THE COUNCIL

Protoveratrines A and B for the purified mixture of the ester alkaloids, protoveratrines A and B, derived from Veratrum album: Veralba (Pitman-Moore Company)

Protoveratrine A and B Maleates for that salt of the ester alkaloids, protoveratrines A and B: Provell Maleate (Eli Lilly & Company)

Rauwolfia for the powdered whole root of Rauwolfia serpentina: Raudixin (E. R. Squibb & Sons)

Trihexyphenidyl Hydrochloride for 3-(1-piperidyl)-1-phenyl-1-cyclohexyl-1-propanol hydrochloride: Artane Hydrochloride (Lederle Laboratories Division)

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.

R. T. Stormont, M.D., *Secretary.*

DERMATOLOGICAL PREPARATIONS OF ACCEPTED ANTIHISTAMINE DRUGS OMITTED FROM N.N.R.

At its annual meeting in 1952, the attention of the Council was focused on the problem of cutaneous sensitivity to the antihistamine drugs. It was recalled that a similar problem previously arose in connection with the topical use of the sulfonamides and penicillin. This led the Council to withdraw its acceptance of topical forms of these anti-infective agents, because their therapeutic value is outweighed by the high incidence of sensitivity reactions and because they are effective against local infections when administered systemically.[1] Accordingly, the Council authorized a restudy of the use of certain antihistamine creams and ointments that had been accepted for the relief of itching dermatoses, especially those having an allergic basis.

The opinions of some leading dermatologists from various sections of the country were polled on the following questions: 1. In your opinion are the reactions on the skin to the use of ointments and creams containing antihistaminic drugs few, frequent, or many? 2. State the preparations causing the most disturbance in your experience in practice and in the clinic. 3. Do you believe the adverse effects from these agents outweigh their usefulness?

The replies to these questions are almost unanimous in concluding: (1) that numerous cases of dermatitis have appeared coincidentally with the use of such preparations, (2) that although this has not been attributed to all of the antihistamine drugs, they are potentially capable of producing cutaneous sensitivity, and (3) that such adverse effects can be considered to outweigh their usefulness at the present time. The majority of those consulted indicated that they either have limited the use of these preparations, or have abandoned them entirely. Regarding topical therapy in general, the suggestion was offered that until all important drugs or those commonly used for internal (systemic) administration are proved to have a low index of sensitization, they should not be employed topically.

In accordance with the foregoing opinions of experienced dermatologists, based upon observations that have accumulated since topical forms of antihistamine drugs were accepted, the Council concluded that, although some of them apparently have been helpful in relieving certain types of pruritus, the risk of contact dermatitis now overshadows their possible efficacy for that purpose and that further evidence is required to establish their usefulness.

On the basis of the foregoing conclusions, the Council voted to discontinue the acceptance of dermatological preparations of all antihistamine drugs, to omit from "New and Nonofficial Remedies" all currently accepted products in that category, and to revise appropriately the affected N.N.R. monographs and the general statement on histamine-antagonizing agents.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Bacitracin (See New and Nonofficial Remedies 1953, p. 45).

Pfizer Laboratories, Division of Chas. Pfizer & Co., Inc., Brooklyn.

Soluble Tablets Bacitracin: 5,000 units.

Butabarbital Sodium (See New and Nonofficial Remedies 1953, p. 251).

The Bowman Bros. Drug Company, Canton, Ohio.

Elixir Butabarbital Sodium: 473 cc. and 3.78 liter bottles. A flavored alcohol solution containing 6.6 mg. of butabarbital sodium in each cubic centimeter.

Tablets Butabarbital Sodium: 16 and 32 mg.

Diethylstilbestrol-U.S.P. (See New and Nonofficial Remedies 1953, p. 368).

The Bowman Bros. Drug Company, Canton, Ohio.

Tablets Diethylstilbestrol: 5 mg.

Estrogenic Substances, Conjugated (See New and Nonofficial Remedies 1953, p. 364).

Premo Pharmaceutical Laboratories, Inc., South Hackensack, N. J.

Tablets Estrifol: 1.25 mg.

Hexachlorophene (See New and Nonofficial Remedies 1953, p. 54).

The Bowman Bros. Drug Company, Canton, Ohio.

Surgical Soap Hexachlorophene: 473 cc. and 3.78 liter bottles. A soap containing 2% hexachlorophene (anhydrous basis).

Central Chemical Company, Inc., Kansas City, Mo.

Liquid Soap Surgi-Cen: 3.78, 18.9, 56.7, 113.4, 132.4, and 208.1 liter containers. A soap containing 1% hexachlorophene.

Hexamethonium Chloride (See New and Nonofficial Remedies 1953, p. 241).

Ciba Pharmaceutical Products, Inc., Summit, N. J.

Syrup Esomid Chloride: 473 cc. bottles. A syrup containing 62.5 mg. of hexamethonium chloride in each cubic centimeter. Preserved with 0.1% sodium benzoate.

Tablets Esomid Chloride: 0.25 gm.

Sodium *p*-Aminosalicylate (See New and Nonofficial Remedies 1953, p. 91).

Intermedico Corporation, Floral Park, L. I., N. Y.

Tablets Pasmed Sodium: 0.5 gm.

THE ST. LOUIS MEETING

In the December 26 issue of THE JOURNAL will be an abstract of the proceedings of the House of Delegates of the American Medical Association at the December, 1953, meeting of the Association. In the organization section of the current issue are several pages of pictures taken at this meeting. In time, the complete proceedings will be available in a booklet that will be obtainable from the office of the Secretary of the Association. In the meantime, mention of a few of the highlights may be of interest to the physicians who did not attend this seventh annual Clinical Meeting.

The House of Delegates received reports from various officers of the Association and standing committees of the House. It also was addressed by the President, Edward J. McCormick of Toledo, Ohio, by the Speaker, James R. Reuling of Bayside, N. Y., and by several guests, including Chester Keefer of Boston, special assistant to Mrs. Oveta Culp Hobby of the Department of Health, Education, and Welfare. After the presentation of reports and resolutions and their consideration by reference committees, the House took important actions on questions relating to social security, voluntary health insurance, medical ethics and unethical practices, medical education, hospital accreditation, and military affairs. Consideration also was given to the supply of interns, the commission on intergovernmental relations, scope of the word "rehabilitation," rural health, hospital-physician relations, simplification of membership classifications, and the training of chiropractors and naturopaths. It also honored the 1953 "General Practitioner of the Year," Joseph I. Greenwell of New Haven, Ky. This was reported in the December 12 issue of THE JOURNAL.

The House passed a resolution reaffirming its opposition to the compulsory coverage of physicians under the Old Age and Survivors Insurance provisions of the Social Security Act and advocated passage of the Jenkins-Keogh bills now pending in Congress. These bills were described as providing for "the development of a voluntary pension program which is equitable, free from compulsion, and satisfies the retirement needs of physicians."

The reference committee report adopted by the House read in part:

"The purpose of these bills is to eliminate the discrimination and inequities which exist under present tax laws by extending the tax deferment privilege to the country's ten million self-employed and also to millions of employees who are not covered by pension plans. The purpose of the resolution is to reaffirm our support of the voluntary pension program provided in the Jenkins-Keogh bills and to reaffirm our strong opposition to the extension of compulsory coverage of physicians and other self-employed persons under Title II of the Social Security Act."

The same committee report urged continued action to obtain passage of the Bricker amendment (S. J. Res. 1) and approved the principle of legislation that would reduce or remove the limitation on the deduction of medical and dental expenses for income tax purposes. It also opposed any further extension of the "Doctor-Draft" law beyond the present expiration date of June 30, 1955 The report read in part "your Committee feels strongly that there should be no further extension of the 'Doctor Draft' Law. We feel that the legislation is discriminatory and urge the Committee on Legislation and the Board of Trustees to actively oppose any further extension."

The House acted to accelerate the development of voluntary health insurance by passing a resolution requesting the Council on Medical Service to proceed immediately with a special study of the problems of catastrophic coverage and coverage for retired persons. The Council was asked to present its findings and recommendations to the House not later than the 1954 Clinical Meeting. According to the resolution adopted: "There are two large groups of citizens for whom improved coverage could be offered under present prepaid medical care plans, namely: (a) those individuals who suffer catastrophic or long-continued and highly expensive illness and whose financial resources are not adequate to meet the cost thereof and (b) those citizens who have retired and are living on small incomes and who are not eligible under presently existing public or private plans." The resolution emphasized the medical profession's "responsibility to make every effort to promote such prepaid medical coverage for all citizens whose circumstances make them eligible."

Another resolution on voluntary health insurance stated: "the American Medical Association condemns all insurance contracts which classify any medical service as a hospital service." The resolution affirmed previous actions of the House defining pathology, radiology, anesthesiology, and physiatry as medical services.

The House approved a revision of one section of the Principles of Medical Ethics of the American Medical Association that clarifies the relationship of physicians to all forms of public information mediums. The revision had been developed by the Council on Constitution and By-Laws and will appear in the revised Principles of Medical Ethics.

In an effort to solve the publicity problems resulting from unethical practices by a small minority of doctors, the House referred to the Board of Trustees a resolution calling for appointment of a special committee with broad professional representation to study all aspects of the problems. The Board was asked to study and implement the intent of the resolution and to report its findings to the House at the June, 1954, meeting in San Francisco.

To clarify misunderstandings among physicians regarding the rules and regulations of the Joint Commission on Accreditation of Hospitals, especially as they concern the role of the department of general practice in a hospital, the House adopted the following resolution:

"That this House of Delegates of the American Medical Association request the Joint Commission on Accreditation of Hospitals to publish an article, or series of articles, in the Journal of the American Medical Association and other official publications circulating among the medical and hospital professions, to acquaint the medical-hospital profession with the regulations, bylaws and their interpretations, and

"That the Commission clarify the methods by which an aggrieved hospital or its staff may appeal a decision with which they are not in agreement."

In the field of medical education, a fourth grant of $500,000 was made by the American Medical Association to the American Medical Education Foundation for financial aid to the nation's medical schools. The foundation reported that its 1953 income now totals $1,174,000 and that the number of contributors now is more than double the total in 1952. Dr. Louis H. Bauer of New York, immediate past president of the American Medical Association, was elected president of the foundation just prior to the opening of the Clinical Meeting. He succeeds the late Dr. Elmer L. Henderson of Louisville, Ky., also a past president of the American Medical Association.

At the opening session of the House, Dr. McCormick in his presidential address made a strong appeal to the nation's physicians for "action that will further full confidence of the public in our profession."

"Good public opinion cannot be bought," he declared. "It must be earned through exemplary conduct and genuine service in the public interest. Whatever money the A. M. A. and its constituent societies spend for public education and public relations is wasted unless individual physicians take wholehearted interest in assuring the success of these ventures."

Dr. Reuling, emphasizing that much serious work remains to be done, warned: "times are just as troubled as when we had blanket bills before Congress which would have socialized the practice of medicine." Dr. Keefer told the House, "the voluntary way has been the most successful in the past and there is no reason to believe it will not continue to be in the future." He urged maximum effort, cooperation, and leadership on the community level. The addresses by Drs. McCormick, Reuling, and Keefer will appear in full in the December 26 issue of THE JOURNAL.

Just prior to the Clinical Meeting the Joseph Goldberger award for outstanding contributions in the fields of clinical nutrition was presented to Dr. *James Somerville* McLester of Birmingham, Ala., a practicing physician for more than 50 years. The award was presented by the American Medical Association through its Council on Foods and Nutrition.

On the scientific side of the Association's meeting were the many excellent exhibits and papers. Too numerous to mention, they can be regarded, nevertheless, as of the caliber anticipated when a program of the meeting was published in THE JOURNAL, October 31. Some of the papers will be published in THE JOURNAL. All were developed with the general practitioner and his practical clinical problems in mind.

The next meetings scheduled for the American Medical Association will be held as follows:

1954 Annual Meeting, June 21-25, San Francisco
1954 Clinical Meeting, November 30-December 3, Miami, Fla.
1955 Annual Meeting, June 6-10, Atlantic City, N. J.
1955 Clinical Meeting, November 29-December 2, Boston
1956 Annual Meeting, June 11-15, Chicago

It is not too early to begin plans for attending some, preferably all, of these meetings.

PERIODIC HEALTH EXAMINATIONS

The growing tendency to recommend an annual physical examination has aroused a great deal of controversy in this country and abroad. As is the case with most arguments, resolution must await the accumulation of facts. Toward this end, encouraging steps are being taken. Baker and co-workers[1] have analyzed the results of 2,178 examinations, including follow-ups in 1,350 persons, mostly business executives, who had no physical complaint. Many of them were sent for examination at the expense of the firms by which they were employed. This indication that corporations are recognizing that the toll of death and disability in their executives is excessive and that something should be done in the way of prevention is in itself encouraging. Following are questions relating to the periodic examination that still need to be answered.

1. What shall constitute a medical "overhaul" in a person with no complaints? In discussing this question Abrahams,[2] a staunch opponent of complete periodic medical examinations, states correctly that it would be absurd to do all the known tests on every subject. That is precisely why Baker and his co-workers would like to see a standardized examination agreed on. Such a standardization would have the advantage that the reports from many observers could be compared and combined for statistical analysis. Abrahams further suggests that rather than an elaborate battery of laboratory and roentgenologic tests a thorough and skillful interrogation of the patients covering each organ system would save both time and money and perhaps accomplish as much. Few, if any, proponents of the annual physical check-up would accept such a limited procedure, valuable as it might be as an essential part of a routine examination. This is indeed a knotty problem, and final agreement on which tests must be included and which may be omitted will

[2] Abrahams, A.: Periodic Medical Overhaul, Lancet 2: 670-671 (Sept. 26) 1953.

not be easily arrived at. Most authorities agree, however, that in subjects over 45 years of age a roentgenogram of the chest, a rectal digital examination, and an electrocardiogram should be included.

2. Is reassurance of a patient after a routine check-up that he has no disease valid? The answer to this question (posed by Abrahams) is: No, not always. No physician is omniscient, and the same question could be asked regarding a patient who seeks to find out whether his epigastric distress indicates a malignant disease or whether his precordial pain indicates heart disease. In how many patients after examination and reassurance has unmistakable evidence of cancer or coronary occlusion subsequently and sometimes within only a few months developed? This question then would seem not to be entirely justified, but it is being asked by those who would do away with periodic check-ups.

3. Do the results of complete medical examination in a large group of patients justify the outlay of time and money and the discomfort to the patients? For this there are some statistics. Of the 1,350 subjects in Baker's series, only 167 were found to have no disease. The authors included as disease only those conditions that were found to be producing symptoms (although not severe enough to have caused the patient to seek medical aid) or which threatened future health. As a result, although dental caries and pes planus were commonly observed the former was considered a disease in only 10 patients and the latter in none. The diseases most commonly found were obesity, anemia, hypertension, osteoarthritis, and hypothyroidism. In addition, many early malignant tumors and precancerous lesions were found and treated. These authors, besides trying to determine the value of these examinations to the patient, are attempting to rate patients as good or poor risks from the standpoint of the interested business firm; for example, a patient who has a poor prognosis would not be considered as a risk to his firm if he were close to the age of compulsory retirement. In another study Portis and his associates[3] discovered a relative hypoglycemia in nearly half of a group of business executives under 50 whose only complaint was chronic fatigue, and of 55 executives in this age group sent for a check-up by their firms only 3 were found to be free of disease; 16 had hypertension and 14 were overweight. These figures would indicate that health examinations when carefully performed by a group of clinicians interested in the prevention of disease can be decidedly worth while.

4. Is it wise to place emphasis on disease instead of health in educating the public? This question (again posed by Abrahams) should not be cast aside lightly. To be constantly concerned about whether one has a disease is in itself a disease and one that may be incapacitating. There is much to be said for enjoying the feelings of well-being without worry. For every person of this temperament who is suddenly struck down by a serious illness there are hundreds who go on enjoying a fuller life primarily because they do not worry over the state of their health; in fact, such an attitude in itself does much to prolong life. What is needed then in patients is the ability to reach a happy medium between lack of normal concern and extreme introspection, and this requires a mature outlook, which is not easily acquired.

THE PLACE OF FORCEPS IN MODERN OBSTETRICS

Jeffcoate,[1] in reviewing the place of forceps in modern obstetrics, calls attention to the fact that early objections to the use of forceps based at first on prejudice or vested interest were quickly justified by the abuse of this method of extraction. Although the use of forceps has regained great popularity, this can be maintained only by the most judicious application of the principles of good obstetrics. Maternal and fetal mortality have been reduced by a combination of advances in medicine (chemotherapy, etc.) and advances in obstetric technique. In hospital deliveries the use of forceps has almost trebled in 25 years. This increase has been at the expense of spontaneous labor rather than of cesarean section and has been an important factor in the reduction of mortality referred to. As Jeffcoate so aptly puts it, "babies previously born dead with forceps are now being delivered alive by cesarean section, while those stillborn as a result of spontaneous delivery are now extracted alive with forceps."

The risks of using forceps have been reduced by changes in technique and changes in indications. Changes in technique include the discarding of all forms of axis traction instruments; substitution of skill for force in exerting traction; the use of episiotomy; correction of the position of the fetal head before or after application of the forceps; the use of local analgesia in place of general anesthesia; and, most important of all, accurate placement of the blades. Even more important than these changes were the changes in indications. The general condemnation of high forceps extractions is extending to midforceps extractions, which should never be attempted in home deliveries. In hospital deliveries all midforceps operations should be regarded as trial operations with the clear understanding that should this maneuver fail a cesarean section will be performed without delay. If this is understood before the forceps are applied, there will be less tendency for the operator to try to force a vaginal delivery; he may abandon this effort, switch to abdominal delivery without loss of face, and thereby in many cases save the life of the baby and perhaps of the mother. The performance of a cesarean section after a trial application of forceps is not the hazardous procedure it was before the discovery of modern chemotherapeutic agents. It is important in determining the indications for the use of forceps to anticipate rather than wait for signs of maternal exhaustion or fetal asphyxia. Uterine inertia is no longer a contraindication to the application of forceps, because postpartum hemorrhage can be effectively controlled with ergonovine. The frequent, almost routine use of forceps on an after-coming head has done much to reduce fetal mortality in breech deliveries. Forceps may also be legitimately used to extract the soft head of the premature infant and thereby reduce the danger of cerebral trauma.

MEDICAL NEWS

ARKANSAS

Cancer Bequests.—By the will of the late Birdie Sparks, Little Rock, the University of Arkansas Medical Center has received $20,000 for purchase of equipment and materials, and the St. Vincent Tumor Clinic, $1,700.

Society News.—The first annual meeting of the Arkansas Obstetrical and Gynecological Society was held at the Hotel Marion in Little Rock, Oct. 31. Dr. William H. Masters, associate professor of obstetrics and gynecology, Washington University School of Medicine, St. Louis, discussed "The Male as an Infertile Problem" and "The Role of Habitual Abortion in Infertility."

Personal.—Dr. Arthur C. Curtis, director, division of tuberculosis control, Arkansas State Health Department, has been assigned as an officer of the U. S. Public Health Service to a two year term of duty at Jimma, Ethiopia. Dr. Clifford H. Cole, director, division of venereal disease control, will act also as the director of the division of tuberculosis control during Dr. Curtis' absence.

Dr. Ellis, Distinguished Citizen.—Dr. Edward F. Ellis of Fayetteville was honored on his 90th birthday by the Washington County Historical Society, which presented a "Distinguished Citizen" citation to him. Dr. Ellis is a past president of the Arkansas Medical Society and a former member of the State Board of Medical Examiners during two gubernatorial administrations. He has served as chief-of-staff of the Fayetteville City Hospital. A charter member of the board of directors of the First National Bank, he was recently reelected to his 50th annual term on the board. He was a member of the Fayetteville school board for 15 years. The Ellis Room in the library of the University of Arkansas Medical School houses a professional library of more than 1,100 books presented by Dr. Ellis.

CALIFORNIA

Study of Plague Vectors.—The School of Tropical and Preventive Medicine of the College of Medical Evangelists at Loma Linda has received $32,300 in grants from the Army Surgeon General's office to continue a study of the control of plague vectors under field conditions. The study began June 1, 1951, and will end May 31, 1954. The appropriation brings the total of grants to $76,500.

Research Laboratory at Los Alamos.—The Los Alamos Scientific Laboratory of the University of California announces completion of its new $1,870,000 health research laboratory. The new building contains laboratories, offices, shop, stockroom, rooms for exposing animals to radiation, and air-conditioned animal quarters. The industrial hygiene group and the biological and medical research group will be housed in the new building.

Infectious Encephalitis.—According to the Department of Health, Education, and Welfare, U. S. Public Health Service, a total of 17 cases of infectious encephalitis in human beings, with laboratory confirmations, had been reported this year in California as of Oct. 24. Seven were the St. Louis type of infection, and the remainder were western equine. All but four occurred in the central valleys, with western equine type of infection in Sacramento Valley and the St. Louis type in the San Joaquin. Of 386 pools of mosquitoes examined from Kern and Fresno Counties, 47 showed the presence of St. Louis (18) and western equine (29) types of virus.

Dr. Pierce Honored.—On Nov. 2 in San Diego, Dr. Georg Warren Pierce, vice-president, board of trustees, St. Franci Memorial Hospital, San Francisco, was guest of honor at dinner given by the American Society of Plastic and Reconstructive Surgery, at which he was presented with th "Special Honorary Citation of the Society." Dr. Pierce i consulting plastic surgeon at Children's Hospital, U. S. Publi Health Service Hospital, Letterman Army Hospital, and th Southern Pacific General Hospital. He is a past president the American Association of Plastic Surgeons and the Cal fornia Society of Plastic Surgeons; past vice-president, Amer can Society of Plastic and Reconstructive Surgery; honorar member, British Association of Plastic Surgeons; member the California Academy of Medicine; and an original membe of the American Board of Plastic Surgery.

CONNECTICUT

Society News.—At the Nov. 24 meeting of the Connectic Rheumatism Society in Waterbury, Dr. Hans Waine, medic director of the New England Arthritis and Rheumatism Assoc ation and lecturer at the Harvard Medical School, Bosto discussed "Management of the Rheumatoid Arthritis Patie in General Practice." Dr. Stanley H. Osborn, Hartford, commissioner of health of the State of Connecticut and honorar president of the society, pointed out the increased faciliti made available in recent years.

IDAHO

Personal.—Dr. Joseph G. Wilson, Moscow, has been chose president of the Idaho Institute of Christian Education, Inc of which he has been a board member for several years.

General Practitioners Scientific Session.—The first annu scientific session of the Idaho chapter of the America Academy of General Practice was held at Twin Falls, Oct. 2 under the presidency of Dr. Franklin C. David, Boise. Speakers included three members of the faculty of the Universit of Utah College of Medicine in Salt Lake City: Dr. Emil G Holmstrom, professor of obstetrics and gynecology, discusse "The Acute Abdomen During Pregnancy" and "Diagnosi and Treatment of Leukorrhea"; Dr. William H. Moretz, associate professor of surgery, presented "Advances in Managemen of the Acute Abdomen" and "Injuries and Infections of th Hand"; and Dr. Harold Brown, associate professor of medicine, "Antibiotic Therapy" and "Management of Congestiv Failure." Drs. J. Woodson Creed and Charles R. McWilliams Twin Falls, conducted a clinical pathological conference. Th program was arranged by Dr. Orvid R. Cutler, Preston.

KENTUCKY

Dr. Coleman's Day.—Dr. Clarence T. Coleman, four-tim mayor of Frankfort and a practicing physician for more tha 40 years, was honored at a celebration of "Doctor Coleman' Day" by the people of Franklin County on his 71st birthday Gov. Lawrence W. Wetherby and other state officials joine in paying homage to Dr. Coleman on the special day officiall proclaimed by the Franklin Fiscal Court. An estimated 1,000 persons participated in the festivities.

LOUISIANA

Society News.—The radiologists of Louisiana have reorganized their association and changed its name to the Radiological Society of Louisiana. The officers are Dr. Henry M. Duhe, New Orleans, president, Dr. Granville M. Riley, Shreveport, vice-president, and Dr. Joseph T. Brierre, New Orleans, secretary-treasurer.

Portrait of Ernest Faust.—Ernest Carroll Faust, Ph.D., has completed a quarter century as professor of parasitology in the Tulane University of Louisiana School of Medicine. His

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

portrait, sponsored by associates and students, was presented to the school following a eulogy by Dr. Henry F. Meleney, research professor of medicine at Louisiana State University, who served with Dr. Faust on the faculty of the Peking Union Medical College of China. According to a release from the university, among other accomplishments cited were authorship of 281 papers and several books, including the first English text on human worm infections, demonstration that gentian violet taken by mouth eliminates liver fluke in its early stages, the first demonstration that diet is an important factor in amebiasis, and work leading to the first demonstration of the effect of antibiotics in amebiasis, and extensive work with the army to control tropical disease during World War II. Dr. Joseph S. D'Antoni, a member of the Tulane faculty, presented the portrait to the school. Dr. Maxwell E. Lapham, dean, accepted the portrait for the school of medicine.

MAINE

Society News.—At its meeting in Augusta, Oct. 21, the Maine Academy of General Practice elected Dr. Howard H. Milliken, Hallowell, president, Dr. Francis A. Fagone, Portland, president-elect, and Dr. Clyde I. Swett, Island Falls, retiring president, a member of the organization's board of directors for a three year term.

MARYLAND

Fellowship in Medicolegal Pathology.—The division of legal medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has established fellowships in medicolegal pathology, open to American citizens, graduates of Class A medical schools with a minimum of one year of formal training in pathology. A basic stipend of $2,500 annually is provided. Inquiries should be directed to Dr. Russell S. Fisher, professor of legal medicine, 700 Fleet St., Baltimore 2.

Exhibit on History of Medicine.—Opening ceremonies for this exhibit, which will continue through Dec. 31, were held Nov. 16 at the Maryland Historical Society Building, 201 W. Monument St., Baltimore. The principal address was by Dr. Thomas Parran, dean, Graduate School of Public Health, University of Pittsburgh, and former Surgeon General, U. S. Public Health Service. Among the items on display are early medical appliances, original manuscripts, portraits of early physicians, views of hospitals, and dental and pharmaceutical materials of an earlier day. The exhibit is open to the public.

Dr. Gottschalk Goes to Ohio.—Dr. Louis A. Gottschalk, Bethesda, research psychiatrist for the Clinical Center of the National Institute for Mental Health, has been named associate professor of psychiatry in the University of Cincinnati College of Medicine. He will also serve as attending psychiatrist at Cincinnati General Hospital and as supervisor in the Central Clinic of the Community Chest. Dr. Gottschalk was previously affiliated with Barnes Hospital in St. Louis, the U. S. Public Health Service Hospital in Ft. Worth, Texas, and Michael Reese Hospital in Chicago. His wife is Dr. Helen C. Reller Gottschalk.

Golden Anniversary.—The Montgomery County Medical Society, celebrating its golden anniversary, was host to physicians from all of Maryland at a meeting of the Medical and Chirurgical Faculty of the State of Maryland at the National Institutes of Health in Bethesda, Oct. 6. Dr. William S. Murphy, Rockville, president of the county society, and Dr. Maurice C. Pincoffs, Baltimore, president of the state society, welcomed the guests. An account of the history of the society was given by one of its oldest members, Dr. Jacob W. Bird, Sandy Spring, who was secretary of the society for 28 years. The general meeting concluded with an address by Dr. Leonard A. Scheele, Washington, D. C., Surgeon General of the Public Health Service, who discussed "Medical Research, the Physicians, and Public Health." Following the meeting, seminars were presented by staff members of the National Institutes of Health.

MASSACHUSETTS

Personal.—Dr. Shields Warren, Newton, pathologist for the New England Deaconess Hospital, Boston, since 1927 and director of the Deaconess Cancer Research Institute, has been elected chairman of the executive committee of the Boston University board of trustees. Dr. Warren has been trustee of the university since 1938 and a member of the executive committee for the past 11 years.——Dr. Douglas A. Ross, formerly of Cambridge, Mass., has been appointed assistant professor, division of physiology, University of Tennessee Medical Units, Memphis.——Dr. Henry R. Viets, Boston, recently gave a lecture, "William Smellie (1697-1763) and His Influence on Obstetrics and Medical Teaching" at the University of Texas Medical Branch, Galveston, and also at the University of Oklahoma School of Medicine, Oklahoma City.

Study of Maternal Deaths.—The Massachusetts Medical Society announces that its committee on maternal welfare, which will begin a new five year program in 1954, is redoubling its efforts to study all maternal deaths in the state. Physicians are urged to inform the committee by telephone immediately of any maternal death. In the western part of the state, call Dr. Arthur F. G. Edgelow, 76 Maple St., Springfield (telephone, Springfield 4-5926); in the eastern section, Dr. John F. Jewett, 319 Longwood Ave., Boston (telephone BEacon 2-3911), Dr. Benjamin F. Cornwall, Salem, Dr. Joel M. Melick, Worcester, or Dr. Robert H. Goodwin, New Bedford. The committee points out that a postmortem examination should be requested in every case. If a pathologist is not locally available, the committee will supply this service without charge.

MISSISSIPPI

Dr. Johansen Honored.—Dr. Frederick A. Johansen, former medical officer in charge of the U. S. Public Health Service Hospital at Carville, La., now retired and living at Long Beach, was an honor guest of the American Legion Auxiliary at the national convention in St. Louis, where he received a distinguished service plaque bearing the following inscription: "Dr. Frederick A. Johansen—in Appreciation of his Devoted Service to the Sick and Unfortunate and his Furtherance of a Better Understanding of Hansen's disease and its Treatment. Presented at the 1953 National Convention, St. Louis, Mo., American Legion Auxiliary."

MISSOURI

Drs. Robert A. and Carl V. Moore to Assume New Posts.—Dr. Robert A. Moore, dean of the Washington University School of Medicine, St. Louis, has been named vice-chancellor in charge of the schools of the health professions at the University of Pittsburgh, which is embarking on a multimillion dollar medical expansion program. He will coordinate teaching, research, and patient care in the hospitals, clinics, and professional schools of medicine, dentistry, pharmacy, nursing, and public health. His specific duties among other things include the development of adequate facilities, selection of distinguished faculties for the five professional schools, and the development of strong education and research programs. Dr. Moore will assume his responsibilities in Pittsburgh on a full-time basis next spring but will begin immediately to institute the program and to supervise further development of the center.

Dr. Carl V. Moore, professor of medicine at Washington University School of Medicine, will succeed Dr. Robert Moore on March 15. Dr. Carl Moore was assistant professor of medicine at Ohio State University, Columbus, from 1935 to 1938 and Research Council fellow in medicine. From 1944 to 1949 he was editor of the *Journal of Laboratory and Clinical Medicine.* He is governor for Missouri of the American College of Physicians and president of the American Society for Clinical Investigation for the year 1953-1954, and in 1946 was president of the Central Society for Clinical Research. He is chairman of the National Research Council

Committee on Blood and Related Problems, chairman of the hematology study section of the U. S. Public Health Service, and chairman of the medical advisory committee of the St. Louis Red Cross Blood Donor Center.

NEVADA

State Medical Election.—At the annual meeting in Elko the Nevada State Medical Association installed Dr. Dwight L. Hood, Reno, as president. Dr. William A. O'Brien, Reno, remains as secretary.

Personal.—"Dr. Eastman Night" was recently observed by the Lions Club of Carlin to honor the 80th birthday of Dr. Claude W. Eastman, who has been the district surgeon for the Southern Pacific and Western Pacific Railroads in Carlin for the past 30 years and has also served the community during this time.

NEW HAMPSHIRE

State Medical Election.—At the annual meeting of the New Hampshire Medical Society, Dr. Albert E. Barcomb, Rochester, assumed the presidency; Dr. Raymond H. Marcotte, Nashua, was elected president-elect; Dr. Louis C. Theobald, Exeter, vice-president; Dr. Leroy S. Ford, Keene, speaker of the House of Delegates; and Dr. James A. Ferguson, Lancaster, vice-speaker of the House of Delegates.

NEW JERSEY

Dr. Rake Appointed Research Professor.—Dr. Geoffrey William Rake, New Brunswick, has been named to a newly created position, research professor of microbiology in medicine in the schools of medicine and of veterinary medicine, at the University of Pennsylvania in Philadelphia. Dr. Rake was director of the Squibb Medical Division for 4 years, and for 12 years headed the microbiology division of the Squibb Institute for Medical Research. He was affiliated with Guy's Hospital in London before coming to the United States. He served as assistant and then instructor in pathology at Johns Hopkins Hospital, Baltimore, and later joined the staff of the Rockefeller Institute in New York. He received the gold medal in medicine of the University of London and has held the Beaney, Berlinger, Hilton, and Stokes prizes, and the Stokes Traveling Fellowship. He was one of the original members of the Virus and Rickettsial Study Section and the Syphilis Study Section of the U. S. Public Health Service.

New Jersey Neuropsychiatric Institute.—The name of the state Village for Epileptics at Skillman has been changed to the New Jersey Neuro-Psychiatric Institute. An active psychiatric treatment program has been inaugurated, and, as beds become available, new categories will be accepted for diagnosis, treatment, and rehabilitation. A treatment program for nonpsychotic alcoholics from the entire state will be centralized at the institute. Neurological patients, for whom no adequate provision has hitherto been available, will be accepted for diagnostic evaluation and promptly released, their treatment to be continued on an outpatient basis. Research at the institute will be under the guidance of the new director, Dr. Nolan D. C. Lewis. Training programs have been established in conjunction with Jefferson Medical College of Philadelphia and the University of Pennsylvania School of Medicine, Philadelphia. Aftercare clinics will follow the released epileptics, and traveling community clinics to assist local physicians with epileptic treatment problems and for screening admissions are being developed.

NEW YORK

Mental Health Campaign.—To promote its campaign for better mental health the New York State Department of Mental Hygiene recently presented at the State Fair in Syracuse a full-sized haunted house. The exhibit dealt with fear. The booklet "Haunted House" is profusely illustrated and discusses "ghosts" of the past, present, and future and the fears they give rise to. The department will supply copies of the booklet to organizations in New York State interested in the promotion of mental health. Single copies are available free to anyone. Requests should be addressed to the Department of Mental Hygiene, State Office Building, Albany.

State Alcoholism Services.—The Mental Health Commission has established grants in aid to sponsor three new alcoholism projects in Binghamton, New York City, and Rochester. A new part-time alcoholism clinic has been opened in Binghamton City Hospital. Under the sponsorship of the Home Term Court in New York City, a combined research service project has been initiated to study the incidence of alcoholism as a factor in marital discord. At Monroe County Penitentiary in Rochester, a 12 month study will be conducted by the sociology department of the University of Rochester under the auspices of the Tuberculosis and Health Association of Rochester and Monroe County to determine what part alcoholism plays in crime.

Award for Work on Xeroradiography.—At the recent annual meeting of the American Roentgen Ray Society in Cincinnati, its top award for the year, the silver medal, was presented to Drs. John F. Roach, professor of radiology at the Albany Medical College, and Herman E. Hilleboe, commissioner, New York State Department of Health, for their work on xeroradiography, a joint project of the State Department of Health, Albany Medical College, and Albany Hospital. Xeroradiography is a new process whereby x-ray images may be obtained through the electrostatic process without the use of films, darkrooms, or chemicals. Drs. Hilleboe and Roach are continuing their studies at the Albany Hospital, where they are conducting a clinical test of the method and comparing its accuracy with that of conventional x-ray films.

Vocational Counseling for Children with Cardiac Disorders.—The New York Heart Association and the American Heart Association are sponsoring a pilot study of educational counseling for children with heart disease or with a history of rheumatic fever, to be conducted at the Vocational Advisory Service, 432 Fourth Ave., New York 16. Nationally, it is estimated that at least 500,000 children of school age have heart disease. The study is planned to provide vocational counseling over a seven year period for a group of 360 children selected from the Manhattan area on the basis of medical, educational, and intellectual criteria. Information relative to the appraisal of these children and their vocational plans will be shared with the referring clinic or physician and other professional workers who are helping the child with his plans. Information may be secured from Edna M. Lawrence, Vocational Advisory Service, 432 Fourth Ave., New York 16; telephone MU 3-2121, Ext. 3. Dr. George Wheatley, vice-president, division of health and welfare, Metropolitan Life Insurance Company, is chairman of the project's planning committee.

Personal.—Dr. Richard E. Lee, assistant professor of clinical medicine, Cornell University Medical College, New York, has been appointed diagnostic consultant of the Standard Oil Company (New Jersey). Dr. Lee is chief, peripheral vascular group, National Health Institute, and physician in charge, hypertension clinic, New York Hospital.——Dr. Mary Steichen Calderone, Great Neck, L. I., has been appointed medical director of the Planned Parenthood Federation of America. She has been connected with the New York City Health Department and the American Public Health Association, has been a school physician in Great Neck, and is on the board of the Mental Health Association of Nassau County. She is the wife of Dr. Frank A. Calderone, who was formerly with the World Health Organization and is now director of health services at the United Nations secretariat.——Dr. J. Mark Hiebert, executive vice-president of Sterling Drug, Inc., has been elected to the board of trustees of Boston University.

New York City

Hospital News.—A cardiovascular surgical conference is held on Tuesdays, 4 p. m., at Montefiore Hospital for Chronic Diseases under the direction of Dr. Elliott S. Hurwitt, chief, surgical division. The conference presents patients to the cardiovascular team to obtain a group decision on the advisability of cardiovascular surgery.

Lecture on Cancer.—Dr. Francesco Ronchese, associate professor of clinical dermatology, Boston University School of Medicine, and dermatologist-in-chief, Rhode Island Hospital, Providence, R. I., will present "The Fluorescence of Cancer Under the Wood Light". at a conference of the New York Institute of Clinical Oral Pathology, New York Academy of Medicine, Dec. 21, 8:30 p. m.

University News.—Dr. William N. Hubbard Jr. has been promoted from assistant to associate dean of New York University College of Medicine of New York University-Bellevue Medical Center and from instructor to assistant professor in medicine on the college faculty. Dr. Hubbard, who joined the college of medicine faculty in 1949, was John Wyckoff fellow in medicine at New York University from July, 1950, to July, 1951.

Award in Oral Surgery.—At a dinner honoring Dr. Theodor Blum, Oct. 28, friends and colleagues established a fund for an annual Theodor Blum oral surgery award, to be given to a senior student of the School of Dentistry of the University of Pennsylvania, Dr. Blum's alma mater. Dr. Blum has been affiliated with several hospitals and clinics. He was the U. S. delegate to the International Dental Congress in Vienna in 1936 and was a member of the editorial board of the *Archives of Clinical Oral Pathology* from 1937 to 1940.

Dr. Muckenfuss Goes to California.—Dr. Ralph Stewart Muckenfuss, deputy commissioner of health for the City of New York since 1948, has been appointed scientific director of the Naval Biological Laboratory, University of California, whose research program is carried out by the university under a contract arrangement with the Navy Department. The laboratory is located at the naval supply depot in Oakland. Dr. Muckenfuss has also been director of the Public Health Research Institute of New York City and of the Bureau of Laboratories, New York City Department of Health. During World War II he received the Legion of Merit medal while serving as a colonel in the European theater.

NORTH CAROLINA

Narcotic Violation.—Dr. David E. Plummer, Thomasville, pleaded guilty, Oct. 20, in U. S. District Court at Salisbury, to a charge of violating the federal narcotic law and was sentenced to serve a term of 12 months.

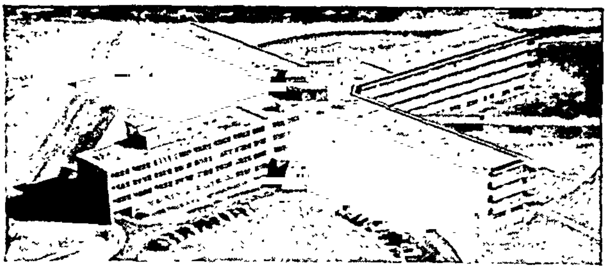
University News.—Dr. F. Douglas Lawrason has been appointed assistant dean of the University of North Carolina School of Medicine in Chapel Hill and assistant professor in the department of medicine. Dr. Lawrason was formerly affiliated with the Yale University School of Medicine, New Haven, Conn., and from 1950 to the present has been professional associate to the division of medical science, National Research Council.——Dr. Frank C. Winter, formerly with the Wilmer Institute of Ophthalmology, Johns Hopkins University, Baltimore, has been named assistant professor of surgery in charge of ophthalmology, and Dr. Robert G. Murray has been appointed instructor in ophthalmology at the University of North Carolina School of Medicine.

OHIO

Dr. Herrmann Honored.—Dr. Louis G. Herrmann, associate professor of surgery, University of Cincinnati College of Medicine, was recently made an honorary fellow of the Academy of Surgery of France in ceremonies in Paris. Dr. Herrmann left Cincinnati in September to attend the Congress of the International Society of Surgery in Lisbon, Portugal, and the 55th French Congress of Surgery in Paris. He served during October as visiting professor to the surgical services of the University of Strasbourg and the University of Lyon, and was invited to address the Swiss Association of Surgery at its annual meeting in Lausanne, Switzerland.

Society News.—At the scientific assembly in Toledo the Northwestern Ohio Medical Association elected Dr. Henry L. Abbott, Tiffin, president, Dr. Boyd W. Travis, Bluffton, vice-president, Dr. Henry B. Larzelere, Toledo, secretary, and Dr. Floyd A. McCammon, Van Wert, treasurer. At the meeting the award of merit was presented by the American Education Foundation to Dr. Edward J. McCormick, Toledo, President of the American Medical Association, as president of the Board of Trustees of the Fred Melvin Douglass Foundation, which was credited with having been of "large material assistance to the American Education Foundation" in providing funds for the promotion of medical education.

Hospital for the Chronically Ill.—The Highland View Cuyahoga County Hospital, Cleveland, was recently opened for the care of the chronically ill. The building, as shown in the illustration, has a capacity of 448 beds, most of which are in four-bed wards; there are eight five-bed wards and a few double and single rooms. The extra wide corridors with hand rails on each side allow for passage of a large number of wheel chair and crutch-walking patients. In addition to the new building the institution includes several older buildings housing ambulatory and semi-ambulatory patients. Plans have been made for renovation of these buildings and for additions that will provide improved facilities. The hospital has an affiliation with Western Reserve University, whereby the school of medicine has teaching and research privileges. The hospital accepts all types of chronically ill patients requiring more than 30 days of hospital care with the exception of the tuberculous, the alcoholic, or the mentally ill. Dr. David R. Weir is director of medical services.



Highland View Cuyahoga County Hospital, Cleveland.

Personal.—Dr. Helen C. Sharp, Cincinnati, is returning to West Pakistan as a medical missionary for the Association of Reformed Presbyterian Missions in Punjab for a term of three years.——Dr. William W. Lynd, Ironton, the fourth Lawrence County physician to complete 50 years' service, was recently honored by the Lawrence County Medical Society at an appreciation dinner in the Patio, and a gold 50 year pin was presented to him.——Dr. Ferdinand F. Fledderjohann, New Bremen, was honored at the October meeting of the Auglaize County Medical Society in commemoration of his completion of 50 years in the practice of medicine. He was presented with a 50 year plaque and certificate from the Ohio State Medical Society.——Dr. Nicholas S. Assali, assistant professor of obstetrics, University of Cincinnati College of Medicine, has been named associate professor of obstetrics and gynecology at the University of California at Los Angeles School of Medicine, where he will also head the Reproductive Physiology Laboratory. Dr. Assali recently returned from Brazil, where he gave five lectures on physiology of pregnancy at the University of São Paulo, Brazil, and one lecture at the University of Brazil at Rio de Janeiro. He also conducted rounds at the department of obstetrics of the Hospital of Clinicas and other hospitals in São Paulo and Rio.

OKLAHOMA

Lectureship Honors Dr. Cook.—Dr. W. Albert Cook, Tulsa, first president of the Tulsa County Medical Society, in 1907, has been honored by the society with the creation of the annual W. Albert Cook lecture, which, featuring a visiting distinguished guest lecturer, will be part of the Annual Founders Day Clinic to be held each fall. Dr. Cook has served as president of the Oklahoma State Medical Association and delegate to the American Medical Association.

SOUTH CAROLINA

Personal.—Dr. Carl B. Epps, Sumter, who has been secretary-treasurer of the Seventh District Medical Society for 32 years, was the recipient of a sterling silver pitcher from the organization at its recent annual meeting. The presentation was made by Dr. Charles R. F. Baker, Sumter, president of the South Carolina Medical Association.

Public Health Laboratory.—A new southeastern public health laboratory, recently opened in Walterboro, will serve the counties of Colleton, Berkeley, Dorchester, Beaufort, Allendale, Jasper, Hampton, Bamberg, and Barnwell. It will be under the local direction of Dr. Holland M. Carter, health officer for Colleton, Dorchester, and Allendale counties.

Memorial Flag.—The U. S. flag, which shrouded the casket of Dr. John Dendley McBrearty when it was returned to his home for burial services during World War II, was recently presented to the Palmetto High School in Williamston by his mother, Mrs. Agnes Dendy McBrearty. She expressed the wish that it might inspire some student to follow the profession of her son and practice in the Pelzer-Williamston area.

TENNESSEE

Society News.—The officers of the Tennessee Radiological Society recently elected during the state medical association meeting are: president, Dr. Joseph McKinney Ivie, Nashville; vice-president, Dr. J. Marsh Frere, Chattanooga; and secretary-treasurer, Dr. George K. Henshall, Chattanooga.

TEXAS

University Activities on Radio.—Radio station KGBC of Galveston is featuring a weekly series of programs describing the teaching, research, and service activities of the University of Texas Medical Branch in Galveston.

Narcotic Violation.—Dr. Leroy Trice, 700 N. Sycamore St., Palestine, pleaded guilty on Oct. 6 in the U. S. District Court at Tyler to a charge of violating the federal narcotic law. On Oct. 16 he was sentenced to serve a term of two years. His sentence was suspended, and he was placed on probation for three years.

Appreciation Day.—Dr. George Sidney Woods, general practitioner in Devine for 42 years, was paid tribute in a "Day of Appreciation" Oct. 1. The local chamber of commerce sponsored a parade, a barbecue, speeches, and gifts in the high school stadium. Dr. Woods was made honorary mayor of Devine. Dr. Robert F. Gossett, chief-of-staff of the Baptist Memorial Hospital, San Antonio, made the principal address, and Dr. Leo E. Peters, Devine, welcomed visiting physicians.

UTAH

Postgraduate Television Clinics.—In cooperation with KDYL-TV, Salt Lake City, the division of graduate and postgraduate medical education, University of Utah College of Medicine, supported in part by a grant from the W. K. Kellogg Foundation, has televised an early morning series of postgraduate clinics weekly from the amphitheater of the Salt Lake General Hospital. Though the broadcast is on an open circuit, the clinics are on a postgraduate level, and announcement of the time of broadcast is made only to physicians. Audience participation in the program is encouraged, and unlisted telephone service directly to the broadcast amphitheater is provided, so that physicians may ask questions during the program. Only the physicians in the Salt Lake area are given the phone number for this type of participation. This series of clinics represents the initial use of open circuit television for postgraduate medical education and is considered an experiment in medical education. Evaluation of the clinics will be published after completion of the present series.

VERMONT

Parents of Blind Children Form Organization.—The Vermont Association for the Blind and the Division for the Blind of the State Department of Social Welfare have endorsed a newly created organization of parents of blind children to help other parents make the adjustment necessary when the child is visually handicapped at birth. Physicians having knowledge of the latter families are requested to refer them to Mr. and Mrs. Samuel Stowell, Rutland, Mr. and Mrs. Robert Russell, Underhill Center, or Mr. and Mrs. Marcel Blouini, Montpelier.

WASHINGTON

University News.—Dr. James W. Haviland, assistant dean of the University of Washington Medical Department, Seattle, on a part-time basis, has been appointed acting dean until a successor is appointed for Dr. Edward L. Turner, who resigned to become secretary of the A. M. A. Council on Medical Education and Hospitals.

Scholarship Fund.—The University of Washington, Seattle, has been notified that a half million dollar legacy was bequeathed it by the late Dr. Everett O. Jones. Under the terms of the trust fund, the annual net income from Dr. Jones' estate ultimately will go to the university to establish and maintain the "Dr. Everett O. Jones Scholarship Fund" in the School of Medicine. Grants and loans to deserving students will be made available from that fund.

Dr. Powers Goes to Lebanon.—Dr. Leland E. Powers, head, department of public health and preventive medicine, University of Washington School of Medicine, Seattle, has resigned to join the faculty of the American University in Beirut, Lebanon. Dr. Powers has been county-city health officer for Port Angeles and Clallam County, Tacoma city health officer, Washington state director of health, and from 1944 to 1946 was chief medical officer in China for the United Nations Relief and Rehabilitation Administration.

WEST VIRGINIA

Society News.—Dr. Walter C. Swann, Huntington, was installed as president of the West Virginia Heart Association at the annual meeting in Charleston; Dr. Francis J. Gaydosh, Wheeling, was named president-elect; Dr. Richard N. O'Dell, Charleston, vice-president; Dr. William E. Bray Jr., Huntington, secretary; and Mr. Ronald E. Plott, Charleston, treasurer.

GENERAL

Traveling Atomic Energy Shows.—The American Museum of Atomic Energy has made available mobile exhibits, which are carried by truck trailer from one city to another. One of the larger traveling shows toured Maryland in November and is scheduled for a December tour in Massachusetts. The exhibits are being offered for use at conventions and other gatherings. Information may be obtained from the American Museum of Atomic Energy, Post Office Box 117, Oak Ridge, Tenn.

Public Health Awards.—At the annual banquet of the Conference of State and Provincial Public Health Laboratory Directors, Nov. 9, in New York, the Kimble Glass methodology research award for outstanding contribution to the field of public health was presented to Dr. Robert A. Nelson Jr., of the department of microbiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, and Manfred M. Mayer, Ph.D., associate professor of microbiology. The award, which includes $500 and an engraved silver plaque, was given in recognition of the Nelson-Mayer method for the diagnosis of syphilis, which has been tested in this country and abroad through the International Cooperating Laboratories of the World Health Organization program.

Foundation Award.—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons offers the annual Foundation Prize of $200 to (a) interns, residents, or graduate students in obstetrics, gynecology, or abdominal surgery, and (b) persons with the degree of doctor of medicine or a scientific degree approved by the prize award committee, who are actively practicing, teaching, or are engaged in research in obstetrics or gynecology. Manuscripts must be presented under a pseudonym, together with a sealed envelope bearing the pseudonym and containing a card showing the name and address of the contestant. Three copies of the double-spaced typewritten manuscript (no more than 5,000 words) must be in the hands of the president of the foundation before April 1. Information may be obtained by writing to the president, Dr. Jean Paul Pratt, 2799 W. Grand Blvd., Detroit.

Society News.—The **American Board of Anesthesiology** at its meeting in St. Paul, Sept. 30, elected Dr. Milton C. Peterson, Kansas City, Mo., and reelected Drs. Meyer Saklad, Providence, R. I., and Curtiss B. Hickcox, Hartford, Conn., as directors, all for six year terms.——At its meeting in Seattle on Nov. 13, the **Pacific Northwest Trudeau Society** elected Dr. James M. Odell, The Dalles, Ore., president, Dr. William S. Barclay, Sardis, British Columbia, president-elect, and Dr. Thomas F. Sheehy Jr., Seattle, secretary-treasurer.——At the annual convention of the **Association of Military Surgeons of the United States** in Washington, D. C., Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, Department of Health, Education, and Welfare, was installed as president, and Major Gen. Joseph I. Martin (MC), U. S. Army, was advanced to the position of first vice-president which Dr. Scheele vacated.——At the annual meeting in Philadelphia on Oct. 15, the **American Board of Dermatology and Syphilology** elected the following officers: Dr. Nelson P. Anderson, Los Angeles, president; Dr. George M. Lewis, New York, vice-president; and Dr. Anthony C. Cipollaro, New York, secretary-treasurer. All correspondence should be addressed to the executive secretary, Miss Janet Newkirk, 66 E. 66th St., New York 21.——The **American Association for the Advancement of Science** will hold a symposium on communication aids for the blind at 9:30 a. m. Dec. 28 in Room E, Mechanics Building, Huntington Ave., Boston, in conjunction with the 120th meeting of the association. Among the topics to be discussed are (1) communication by braille and recordings, (2) communication aspects of visual prosthesis with application to stepdown detection, and (3) recent development of travel aids for the blind.

Pan American Sanitary Organization.—At the recent meeting in Washington, D. C., the directing council of the Pan American Sanitary Organization authorized a budget of $2,100,000 for the year 1954, for continuation of the health programs to be carried out with the guidance of the bureau. The council also approved the preliminary draft of a program and $2,150,000 budget for 1955, submitted by Dr. Fred L. Soper, director of the bureau. The council adopted the following guiding principles for continuous, long-range planning to serve the more basic public health needs of the member countries: the bureau is to base such planning on a continuous survey and evaluation of the needs and resources of the member states, in order better to assist them in strengthening their fundamental health services. Increasing emphasis is to be placed on the training of health personnel, and the bureau is to give its technical orientation in the planning and operation of individual and regional programs for the eradication of such communicable diseases as urban yellow fever, malaria, smallpox, syphilis, and yaws.

The bureau informed the directing council that the incidence of smallpox constitutes a serious problem in the Western Hemisphere. From 1948 to 1952, 85,900 cases with 14,200 deaths from smallpox were reported to the bureau by the health administrations of 17 countries. The bureau stressed, however, that the system of reporting is incomplete and does not reflect the full scope of the problem. Other problems discussed included (1) the difficulty of obtaining the services of highly competent technical personnel, (2) the growing multiplicity of agencies that approach the various governments in regard to public health programs, and (3) difficulties encountered by a number of member countries in obtaining sufficient quantities of residual insecticides and on equitable terms.

Visiting Scientists.—Gustav Asboe-Hansen of the Laboratory for Connective Tissue Research, University of Copenhagen, will be in the United States from Feb. 15 to March 30, 1954, to attend the 5th Conference on Connective Tissues, Feb. 17-19 at Princeton, N. J. His program is being arranged by the Josiah Macy Jr. Foundation, New York. His possible lecture topics include "Hormonal Effects on Connective Tissues" and "The Mast Cell: Morphology and Physiology."——Prof. Hans A. Krebs, M.D., F.R.S., professor of biochemistry, University of Sheffield, and director of the Medical Research Council unit for research on cell metabolism, will deliver lectures from the end of February to April, 1954, at Johns Hopkins University, Baltimore, the University of Chicago, and the University of Wisconsin, Madison.——Kurt A. G. Mendelssohn, F.R.S., university demonstrator, Clarendon Laboratory, Oxford, England, is attending the International Conference on Low Temperatures, Houston, Texas, Dec. 17-22, and will be at Stanford University, Jan. 7, and Berkeley, Calif., Jan. 8.——Dr. C. B. McKerrow, member of the scientific staff of the Medical Research Council, the National Institute for Medical Research, London, England, will be in the United States until August, 1954. He is presently working with Dr. Arthur B. Otis at Johns Hopkins University School of Medicine, Baltimore, and plans to make various visits on behalf of the Medical Research Council. Information may be had from the U. K. Scientific Mission, 1800 K St., N.W., Washington, D. C., concerning his itinerary, which includes Montreal, Canada; Baltimore; Boston; Rochester, N. Y.; Rochester, Minn.; Philadelphia; New York; Saranac Lake, N. Y.; Pittsburgh; and Washington, D. C.——Dr. J. G. Millichap (℅ Dr. Randolph K. Byers, Department of Neurology, Children's Medical Center, Boston) and Dr. Sloane-Stanley (℅ Dr. Jordi Folch-Pi, McLean Hosptal, Waverley, Mass.), both of the Medical Research Council in London, England, and both holders of the Eli Lilly Traveling Fellowship, will be in the United States until October, 1954.

Educational Television Stations.—In its first annual report, the National Citizens Committee for Educational Television states that two noncommercial stations are already telecasting (KUHT, Houston, Texas, and KUSC, Los Angeles), that 27 other noncommercial television stations are expected to be on the air by the end of 1954, that in 25 other communities plans are so well finished that operating stations should become realities in the near future, and that 86 other communities have well-finished plans for noncommercial television stations but no target date has been set for operations. The National Citizens Committee for Educational Television and the joint committee on educational television are financed by the Ford Foundation's Fund for Adult Education. The former committee was established to work with civic and citizen groups desiring to build educational television stations on the 245 channels that the Federal Communications Commission has reserved for noncommercial telecasting. The former committee has published a pamphlet, entitled "Tales of Seven Cities" (Cincinnati, St. Louis, San Francisco, Seattle, Pittsburgh, Wilmette, Ill., and Philadelphia), which shows the variety and similarity of problems in organizing civic and citizen support to build an educational television station. In the Wilmette story it is said that a group of parents was organized to watch every children's television program for one week starting on Christmas Day. During the seven day period these startled parents saw "77 murders, 53 shootings, 30 gunfights, 7 kidnappings, 59 fist fights, 2 knifings, 22 sluggings, 3 whiplashings, 2 poisonings, 2 bombings, 3 murders by poison darts, a man hit over the head with a shovel and another killed by a train, an attempted lynching, a man clawed by a tiger, a suicide, a girl locked in a vault, a boy beaten by his uncle, a man thrown over a cliff, 3 men locked in a safe, and a man blown up in an ammunition dump. This grisly catalogue of plain and fancy crime included only violence wreaked on individuals without counting mass deaths such as the burning of a native village, a falling dirigible, and a ship fire." In Wilmette it was decided that the time had come to act. Civic leaders, educators, clergymen, PTA members, and others were solicited to join a Citizens Committee for Educational Television. At a meeting held to further this cause, it was agreed to conduct a campaign to raise funds, and, before the drive was underway, almost everybody in Wilmette was helping, and 80% of the families solicited contributed funds. The sponsoring group later became the Chicago Educational Television Association. Copies of the pamphlet can be obtained from the National Citizens Committee for Educational Television, Ring Building, Washington 6, D. C.

PHILIPPINE ISLANDS

Heart Association Sponsors Lecture and Award.—The recently formed Philippine Heart Association, an affiliate of the Philippine Medical Association and the International Cardiological Society, sponsors annually the Ricardo D. Molina lecture and the William Burke award. The award includes a gold medal, a one-year free associate membership, and a special additional gift. The Molina lectureship was inaugurated at the first annual heart day, Feb. 14, by a former classmate of the late Dr. Molina, Dr. Antonio G. Sison, emeritus professor of medicine, University of the Philippines College of Medicine, who discussed "Elements Affecting the Prognosis of Heart Diseases." The first Burke awards were won by interns R. Varias and Dedicacion Agatep-Reyes of the University of the Philippines and the University of Santo Tomas colleges of medicine, respectively.

FOREIGN

Medical Meeting in France.—The Medical Days of France and the French Union will be held in Paris April 21-25, 1954, under the chairmanship of Prof. C. Lian, member of the National Academy of Medicine, 19, rue de Bourgogne, Paris 7. The program will include discussions on (1) prolongation and bettering of life by prophylaxis of atherosclerosis, (2) diseases of nutrition, endocrine glands, and digestive tract, (3) fight against infectious diseases and foreign diseases, (4) fight against professional and social diseases, (5) surgery and betterment of life, and (6) sports and rehabilitation in betterment of life. The program of festivities includes an evening of medical films, excursions in the vicinity of Paris, and visits to important points in the city.

CORRECTIONS

Instrument for Endotracheal Anesthesia During Oropharyngeal Surgery.—In the article by this title in The Journal, Nov. 14, 1953, page 1017, succinylcholine chloride is enumerated among drugs used for anesthesia. This was a typographic error, and it should not be inferred that succinylcholine chloride is an anesthesia agent, per se, but simply an adjunct to anesthesia.

Clinical Application of Current Tests of Renal Function.—In the article by this title in The Journal, Dec. 5, 1953, the last paragraph in the article, on page 1249, should read as follows: "In view of the multiplicity of renal functions and the fact that in renal disease these may vary independently of each other, it is evident that no single test is adequate for complete assessment of the over-all functional capacity of the kidneys."

Ménière's Disease.—In the answer to the query by this title in The Journal, Nov. 21, 1953, page 1142, the first two words should have read "Dimenhydrinate (Dramamine)."

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

Annual Congress on Medical Education and Licensure, Palmer House, Chicago, Feb. 7-9. Dr. Edward L. Turner, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, Shamrock Hotel, Houston, Texas, Feb. 1-3. Dr. Alan G. Cazort, 1425 West 7th St., Little Rock, Ark., Secretary.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16. *Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.*

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Jan. 15. Sec., Dr. Leonard T. *Furlow, 600 S. Kingshighway, St. Louis 10.*

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: Written examination (Part I) and review of case histories for all candidates will be held in various cities of the United States, Canada, and military centers outside the continental United States on Feb. 5. Case abstracts are to be sent by the candidate to the Secretary as soon as possible. Application for reexamination in Part II must be made prior to Feb. 1 of any year. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 25-26, 1954. Final date for filing applications was July 1. *Practical.* San Francisco, June 25-29; New Orleans, Feb. 5-11, 1955. Final date for filing application for 1955 written examination is July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Boston, May 17-21. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pediatrics: *Written.* Selected Places. Jan. 15. This is the only written examination which will be given during 1954. *Oral.* Washington, D. C., *Feb. 19-21; Des Moines, March 19-21;* New York City, May 1-3; San Francisco, June 25-27; Chicago, Oct. 8-10 and New Haven, December.

American Board of Psychiatry and Neurology: Chicago, May 10-11. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Spring 1954. Final date for filing application was Dec. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Urology: *Oral-clinical and pathology.* Chicago, Feb. 17-20. Sec., Dr. Harry Culver, 30 Westwood Road, Minneapolis 16.

Board of Thoracic Surgery: *Written.* Various centers throughout the country. Feb. 26. Final date for filing application is Jan. 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Street, Detroit, Mich.

week starting on Christmas Day. During the seven day period these startled parents saw "77 murders, 53 shootings, 30 gunfights, 7 kidnappings, 59 fist fights, 2 knifings, 22 sluggings, 3 whiplashings, 2 poisonings, 2 bombings, 3 murders by poison darts, a man hit over the head with a shovel and another killed by a train, an attempted lynching, a man clawed by a tiger, a suicide, a girl locked in a vault, a boy beaten by his uncle, a man thrown over a cliff, 3 men locked in a safe, and a man blown up in an ammunition dump. This grisly catalogue of plain and fancy crime included only violence wreaked on individuals without counting mass deaths such as the burning of a native village, a falling dirigible, and a ship fire." In Wilmette it was decided that the time had come to act. Civic leaders, educators, clergymen, PTA members, and others were solicited to join a Citizens Committee for Educational Television. At a meeting held to further this cause, it was agreed to conduct a campaign to raise funds, and, before the drive was underway, almost everybody in Wilmette was helping, and 80% of the families solicited contributed funds. The sponsoring group later became the Chicago Educational Television Association. Copies of the pamphlet can be obtained from the National Citizens Committee for Educational Television, Ring Building, Washington 6, D. C.

PHILIPPINE ISLANDS

Heart Association Sponsors Lecture and Award.—The recently formed Philippine Heart Association, an affiliate of the Philippine Medical Association and the International Cardiological Society, sponsors annually the Ricardo D. Molina lecture and the William Burke award. The award includes a gold medal, a one-year free associate membership, and a special additional gift. The Molina lectureship was inaugurated at the first annual heart day, Feb. 14, by a former classmate of the late Dr. Molina, Dr. Antonio G. Sison, emeritus professor of medicine, University of the Philippines College of Medicine, who discussed "Elements Affecting the Prognosis of Heart Diseases." The first Burke awards were won by interns R. Varias and Dedicacion Agatep-Reyes of the University of the Philippines and the University of Santo Tomas colleges of medicine, respectively.

FOREIGN

Medical Meeting in France.—The Medical Days of France and the French Union will be held in Paris April 21-25, 1954, under the chairmanship of Prof. C. Lian, member of the National Academy of Medicine, 19, rue de Bourgogne, Paris 7. The program will include discussions on (1) prolongation and bettering of life by prophylaxis of atherosclerosis, (2) diseases of nutrition, endocrine glands, and digestive tract, (3) fight against infectious diseases and foreign diseases, (4) fight against professional and social diseases, (5) surgery and betterment of life, and (6) sports and rehabilitation in betterment of life. The program of festivities includes an evening of medical films, excursions in the vicinity of Paris, and visits to important points in the city.

CORRECTIONS

Instrument for Endotracheal Anesthesia During Oropharyngeal Surgery.—In the article by this title in THE JOURNAL, Nov. 14, 1953, page 1017, succinylcholine chloride is enumerated among drugs used for anesthesia. This was a typographic error, and it should not be inferred that succinylcholine chloride is an anesthesia agent, per se, but simply an adjunct to anesthesia.

Clinical Application of Current Tests of Renal Function.—In the article by this title in THE JOURNAL, Dec. 5, 1953, the last paragraph in the article, on page 1249, should read as follows: "In view of the multiplicity of renal functions and the fact that in renal disease these may vary independently of each other, it is evident that no single test is adequate for complete assessment of the over-all functional capacity of the kidneys."

Ménière's Disease.—In the answer to the query by this title in THE JOURNAL, Nov. 21, 1953, page 1142, the first two words should have read "Dimenhydrinate (Dramamine)."

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 N Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

Y., April 18, 1903; Medical College of Virginia, Richmond, 1930; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; past president of the National Association of Private Psychiatric Hospitals; director and consultant at the River Crest Sanitarium in Astoria; consultant and formerly consultant at the Belle Mead (N. J.) Sanatorium; associate attending psychiatrist at Queens General Hospital in Jamaica; died in Forest Hills Oct. 25, aged 50, of cardiovascular disease.

⊕ *Indicates Member of the American Medical Association.*

Waldapfel, Richard ⊕ Grand Junction, Colo.; born April 2, 1895; Medizinische Fakultät der Universität, Vienna, Austria, 1921; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, Colorado Otolaryngological Society, and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital and the Veterans Administration Hospital; died in the Presbyterian Hospital, Denver, Sept. 26, aged 58, of carcinoma of the pancreas.

Strickler, Albert ⊕ Philadelphia; born Sept. 13, 1886; Jefferson Medical College of Philadelphia, 1907; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; formerly professor of dermatology and syphilology at Temple University School of Medicine; founder of the Skin and Cancer Hospital, where he was medical director for many years; author of "The Skin: Its Care and Treatment" and "Textbook on Diseases of the Skin and Syphilis"; died Nov. 8, aged 67.

Doran, Martha Venetia ⊕ Northampton, Mass.; born in Iroquois, Ontario, Canada, April 18, 1900; Woman's Medical College of Pennsylvania, Philadelphia, 1943; member of the Medical Society of the State of North Carolina; certified by the National Board of Medical Examiners; assistant physician at Smith College since 1950; served in a similar capacity for three years at the Woman's College of the University of North Carolina in Greensboro; died in the Harkness Pavilion of the Columbia Presbyterian Medical Center in New York, Nov. 2, aged 53.

Aird, John William ⊕ Long Beach, Calif.; University of California Medical School, San Francisco, 1893; fellow of the American College of Surgeons; member and past president of the Utah State Medical Society; formerly practiced in Provo, Utah, where he was affiliated with the Utah State Hospital and was owner and medical director of the Aird Hospital; died Oct. 28, aged 90.

Allen, Joseph R., Urbana, Ill.; Barnes Medical College, St. Louis, 1898; died Oct. 24, aged 80.

Atwood, Abner Lowe ⊕ Birmingham, Ala.; University of Nashville Medical Department, 1907; member of the American Urological Association; on the staff of the South Highlands Infirmary and for many years on the staff of the Hillman Hospital; on the courtesy staff of Baptist, Carraway Methodist, and East End Memorial hospitals; died Nov. 4, aged 75, of cerebral thrombosis.

Bailey, Desmond Mark ⊕ Carbondale, Pa.; Jefferson Medical College of Philadelphia, 1928; member of the staff of Carbondale General Hospital, and the Wayne County Memorial Hospital in Honesdale; died in Mount Sinai Hospital, New York, Aug. 19, aged 50, of coronary disease.

Baxter, James Hubert ⊕ Ashburn, Ga.; Atlanta College of Physicians and Surgeons, 1908; for many years secretary-treasurer of the Turner County Medical Society; served on the city council; died Oct. 13, aged 74.

Baxter, Lewis Thomas ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1920; member of the Industrial Medical Association; for many years physician and surgeon for the *Chicago Daily News;* affiliated with Alexian Brothers Hospital; died Nov. 12, aged 57, of carcinoma of the spine.

Bechtol, Emery Alvin, Montpelier, Ohio; Michigan College of Medicine and Surgery, Detroit, 1892; served during World War I; died Sept. 14, aged 83.

Beebe, Jay Lee ⊕ Laguna Beach, Calif.; Northwestern University Medical School, Chicago, 1903; an Associate Fellow of the American Medical Association; died Oct. 21, aged 79, of coronary occlusion.

Bechler, Louis L., Chicago; Northwestern University Medical School, Chicago, 1900; died in the Illinois Central Hospital Nov. 7, aged 75, of acute papillary necrosis of the kidneys and diabetes mellitus.

Bell, Robert Fleming, Cleveland; University of Buffalo School of Medicine, 1945; certified by the National Board of Medical Examiners; at one time affiliated with Sunny Acres, Cuyahoga County Tuberculosis Hospital; served as a medical missionary in Ethiopia, Africa; died in Chicago Oct. 28, aged 35.

Benton, George R. ⊕ Fremont, N. C.; Medical College of Virginia, Richmond, 1901; died in the Wayne Memorial Hospital, Goldsboro, Aug. 31, aged 74, of carcinoma of the colon.

Benz, Alvin Hermann ⊕ Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1931; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; served during World War II; on the staff of St. Joseph's Mercy Hospital in Ann Arbor and the Beyer Memorial Hospital in Ypsilanti; died Aug. 20, aged 46.

Brown, Barton Levi, Penn Wynne, Pa.; Jefferson Medical College of Philadelphia, 1891; died Oct. 16, aged 88, of heart disease.

Caccini, Attilio Mario ⊕ Major, U. S. Army, retired, New York City; Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia, Italy, 1900; served during World War I; entered the regular army as a major in the medical corps of the U. S. Army on Sept. 8, 1920; retired June 29, 1922; died Aug. 27, aged 77, of arteriosclerotic heart disease.

Campau, George Henry ⊕ Detroit; Detroit College of Medicine and Surgery, 1917; served during World War I; on the staff of the Providence Hospital, where he died Nov. 2, aged 60, of cerebrovascular accident and arteriosclerosis.

Carroll, Gerald John ⊕ New York City; Fordham University School of Medicine, New York, 1919; served on the staffs of Morrisania Hospital and Union Hospital, where he died Nov. 4, aged 58, following rupture of a diverticulum.

Carter, Curtis Braxton ⊕ Columbus, Ga.; Medical College of Alabama, Mobile, 1890; for many years practiced in New York City, where he was affiliated with the Bellevue Hospital; served on the staff of the City Hospital; died Oct. 7, aged 85, of cerebral hemorrhage.

Carver, William Franklin ⊕ Fort Dodge, Iowa; Hospital College of Medicine, Louisville, 1893; past president of the Webster County Medical Society; affiliated with St. Joseph Mercy Hospital and the Lutheran Hospital, where he died Oct. 28, aged 83, of arteriosclerotic heart disease and uremia.

Cary, Eugene, San Mateo, Calif.; Rush Medical College, Chicago, 1912; specialist certified by the American Board of Obstetrics and Gynecology; formerly practiced in Chicago, where he was affiliated with St. Luke's Hospital; died Nov. 5, aged 66.

Causey, Frederick Archibald, Jacksonville, Ill.; St. Louis University School of Medicine, 1914; formerly assistant managing officer of the Chicago State Hospital; for many years affiliated with Jacksonville State Hospital; served as managing officer of the Lincoln (Ill.) State School and Colony; died in the Community General Hospital, Sterling, Nov. 2, aged 69.

Cayley, Frank Joseph ⊕ Indianapolis; University of Illinois College of Medicine, Chicago, 1913; died in the Central State Hospital Sept. 18, aged 66, of angina pectoris.

Caywood, James Robert ⊕ Piqua, Ohio; Starling Medical College, Columbus, 1897; on the staff of the Memorial Hospital, where he died July 3, aged 81, of acute myocardial infarction.

Colehour, Samuel Phillip ⊕ Mount Carroll, Ill.; National Medical College, Chicago, 1899; died Aug. 10, aged 77.

Craddock, Paul Tulane, Rochester, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1950; served during World War II; resident at the Strong Memorial Hospital; died Sept. 17, aged 34.

Currer, Paul Richard ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1942; member of the American Academy of General Practice; served during World War II; died in Ashland Aug. 22, aged 36, of ruptured appendix and peritonitis.

d'Avignon, Francis Wright ⊕ Lake Placid, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1943; interned at the Royal Victoria Hospital in Montreal; served during World War II; died Aug. 27, aged 36, of acute coronary occlusion.

Dinan, Joseph Francis, Wakefield, Mass.; Boston University School of Medicine, 1936; died in the Faulkner Hospital, Boston, Oct. 8, aged 47, of acute adrenal insufficiency and congenital heart disease.

Donathan, Earl Raymond ⊕ Knoxville, Tenn.; University of Tennessee College of Medicine, Memphis, 1935; fellow of the International College of Surgeons; died July 27, aged 45, of a heart attack.

Dowson, Albert Wilson, Evanston, Ill.; Jenner Medical College, Chicago, 1915; died Aug. 11, aged 59, of coronary sclerosis.

Dumm, Colin Marcus, Erie, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1900; died in the Veterans Administration Center, Dayton, Ohio, Sept. 24, aged 78.

Duncan, Will Cunningham ⊕ Los Angeles; Northwestern University Medical School, Chicago, 1915; affiliated with California Lutheran and the Queen of Angels hospitals; died Sept. 24, aged 70, of carcinoma of the tongue.

Erb, Howard Renninger ⊕ Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1940; specialist certified by the American Board of Neurological Surgery; served during World War II; formerly a fellow in neurosurgery at Mayo Foundation in Rochester, Minn.; died Oct. 23, aged 38.

Farthing, Robert R. ⊕ Ozark, Mo.; St. Louis College of Physicians and Surgeons, 1901; died Sept. 24, aged 78, of coronary thrombosis.

Furusawa, Takashi, Los Angeles; Osaka Imperial University Medical Faculty, Osaka, Japan, 1899; Chicago College of Medicine and Surgery, 1916; died Sept. 29, aged 77, of a heart attack.

Glazer, Henry G. ⊕ New York City; Long Island College Hospital, Brooklyn, 1921; specialist certified by the American Board of Ophthalmology; for many years on the staff of the Bronx Eye and Ear Infirmary; died in the Beth Israel Hospital Nov. 6, aged 56, of bacteremia.

Good, Benjamin F. ⊕ Lancaster, Pa.; Baltimore Medical College, 1900; died Oct. 23, aged 81.

Granata, Tancredi Giovanni, Providence, R. I.; Tufts College Medical School, Boston, 1915; served with the Veterans Administration; died Sept. 17, aged 62, of myocardial infarction.

Granger, William Leonard ⊕ Chappaqua, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1932; died Aug. 20, aged 51, of pulmonary edema, coronary sclerosis, and cardiac decompensation.

Korb, David Adam, Cincinnati; Medical Department of the University of Cincinnati, 1910; died Sept. 4, aged 69.

Kupelian, Nessib Simon ⊕ Pownal, Maine; Medical School of Maine, Portland, 1916; member of the New England Society of Psychiatry; medical superintendent of Pownal State School; died in the Central Maine General Hospital, Lewiston, Aug. 28, aged 67, of cerebral thrombosis.

Lane, Irvin J., Ossining, N. Y.; New York Homeopathic Medical College, New York, 1883; director of the Westchester County Savings and Loan Association; died in Middletown Oct. 27, aged 92.

Lanzafame, Sare Anthony ⊕ Farmington, Mo.; St. Louis University School of Medicine, 1941; county health officer; served at State Hospital; died in Barnes Hospital, St. Louis, Nov. 1, aged 39, of a heart attack.

Lindt, Harriet L., South Bend, Ind.; John A. Creighton Medical College, Omaha, 1900; died Aug. 10, aged 75, of metastatic pulmonary sarcoma.

Lyda, Gideon Colwell, Atlanta, Mo.; Kentucky School of Medicine, Louisville, 1888; died in the Woodland Hospital, Moberly, Sept. 5, aged 88.

McCall, James Herald, Lake City, Mich.; Detroit College of Medicine, 1911; served during World War I; at one time connected with the Michigan State Health Department; served as health officer of Marshall County, W. Va.; for many years coroner of Missaukee County; died Oct. 10, aged 69.

MacKenzie, Ian ⊕ Tulsa, Okla.; McGill University Faculty of Medicine, Montreal, Canada, 1927; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the International College of Surgeons and the American College of Surgeons; formerly director of the Hillcrest Polio Center; affiliated with St. John's and Hillcrest Memorial hospitals; died Oct. 12, aged 50, of injuries received in an automobile accident.

Matternes, James G. ⊕ Sinking Spring, Pa.; Jefferson Medical College of Philadelphia, 1897; served during World War I; died Oct. 28, aged 84, of cerebral thrombosis.

Mead, Franklin Braidwood ⊕ Riverside, Calif.; Northwestern University Medical School, Chicago, 1938; formerly a fellow in surgery at Mayo Foundation in Rochester, Minn.; member of Sigma Xi and of the Alumni Association of the Mayo Foundation; on the staff of the Riverside Community Hospital; died Oct. 28, aged 45, of mitral valvulitis with insufficiency.

Moyer, Jacob C. ⊕ Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; L.R.C.S., Edinburgh, Scotland, 1914; died Oct. 4, aged 74, of coronary occlusion.

Null, Frederick Folket ⊕ Hawarden, Iowa; Sioux City (Iowa) College of Medicine, 1907; member of the American Academy of General Practice; affiliated with Hawarden Community Hospital, where he died Oct. 15, aged 75, of myocarditis.

Oliver, Elbert Wilbur, Miami Springs, Fla.; Marion-Sims College of Medicine, St. Louis, 1893; member of the American Society of Anesthesiologists; died in the Jackson Memorial Hospital, Miami, Sept. 21, aged 79, of duodenal ulcer.

Oppenheimer, Arnold ⊕ San Francisco; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1919; died in the University of California Hospital Aug. 20, aged 61, of acute myocardial infarction.

Pharris, Crit, Glastonbury, Conn.; University of Tennessee College of Medicine, Memphis, 1929; member of the American Public Health Association and the Industrial Medical Association; for many years associated with the United Aircraft Corporation; died in Hartford (Conn.) Hospital July 30, aged 52, of coronary thrombosis.

Randall, Arthur G. ⊕ Providence, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; died in St. Joseph's Hospital Nov. 7, aged 82, of carcinoma of the rectum.

Rizzo, Frank ⊕ Grosse Pointe Park, Mich.; Wayne University College of Medicine, Detroit, 1929; on the staff of St. Joseph Mercy Hospital in Detroit, where he died Sept. 13, aged 49, of rheumatic heart disease and pulmonary thrombosis.

Rosen, Harold Leon, Brooklyn; Tulane University of Louisiana School of Medicine, New Orleans, 1944; served during World War II; died in White Sulphur Springs, N. Y., Aug. 28, aged 35, of amyotrophic lateral sclerosis.

Salter, Paul Pullen ⊕ Eufaula, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1916; member of the Southeastern Surgical Congress and the American Academy of General Practice; served during World War I; at one time field director of sanitation for the state board of health; a trustee of the University of Alabama; owner of the Salter Hospital; died in New Orleans Nov. 3, aged 62, of carcinoma of the prostate.

Sill, Joseph, Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; served during World War I; at one time practiced in Detroit, where he was affiliated with the Harper Hospital; died Oct. 19, aged 78, of generalized arteriosclerosis and terminal bronchopneumonia.

Smith, Thomas Caesar, Washington, D. C.; Howard University College of Medicine, Washington, 1909; formerly on the board of directors of the Industrial Bank of Washington; died in Freedman's Hospital Nov. 1, aged 75.

Staines, Albert G., St. Clair Shores, Mich.; Detroit College of Medicine and Surgery, 1917; died in the Providence Hospital, Detroit, Sept. 19, aged 71, of coronary thrombosis.

Steinhauser, Charles Gilbert, Gowanda, N. Y.; University of Michigan Homeopathic Medical School, Ann Arbor, 1912; died Aug. 11, aged 70, of uremia, nephrosclerosis, and diabetes mellitus.

Strasner, Thomas J., Nashville, Ark. (licensed in Arkansas in 1903); died Oct. 18, aged 84.

Stroup, Paul Eugene, Miami, Fla.; Jefferson Medical College of Philadelphia, 1919; died Sept. 23, aged 59, of coronary disease.

Sutton, John Chalmers ⊕ New Brighton, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1902; served as president of the staff of Providence Hospital in Beaver Falls and Beaver Valley General Hospital; died Oct. 11, aged 75, of carcinoma of the throat.

Sweet, Charles Frederick ⊕ Pawtucket, R. I.; Harvard Medical School, Boston, 1894; at one time superintendent of health, city physician, and police surgeon of Central Falls; associate medical examiner for the Pawtucket-Central Falls district from 1912 until 1932 and the medical examiner from 1932 to 1936; on the consulting staff, Memorial Hospital; died Oct. 19, aged 84, of chronic ulcerative colitis and arteriosclerotic heart disease.

Thomson, Arthur Milton, Cherokee, Iowa; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; died in Minneapolis Sept. 18, aged 75, of myocardial infarction.

Tinstman, Abraham Lincoln, Cleveland; Western Pennsylvania Medical College, Pittsburgh, 1896; died Nov. 2, aged 93, of uremia, pyelonephritis, and hypertrophy of the prostate.

Toomajan, Harry John ⊕ Grayslake, Ill.; Loyola University School of Medicine, Chicago, 1926; served during World War II; affiliated with St. Therese's Hospital and Lake County General Hospital in Waukegan, where he died Nov. 11, aged 55, of carcinoma of the left lung.

Van Norden, William Erickson, Plainfield, N. J.; Hering Medical College, Chicago, 1913; practiced in Chesapeake City, Md., for many years; died in the Muhlenberg Hospital Oct. 24, aged 90, of arteriosclerotic heart disease and pneumonia.

Vaught, John Lester ⊕ Dos Palos, Calif.; Creighton University School of Medicine, Omaha, 1938; on the staff of the Dos Palos Hospital; died in San Francisco Oct. 18, aged 41, of cerebral hemorrhage.

Walz, Frank Gebhard ⊕ Buffalo; University of Buffalo School of Medicine, 1909; served during World War I; member of the Association of School Physicians; for many years physician for the board of education, served on the U. S. Board of Examining Surgeons and examining physician for the Metropolitan Insurance Company; on the staff of the Sisters of Charity Hospital, where he died Oct. 15, aged 66, of arteriosclerosis and pulmonary edema.

Watkins, Martin Lucius ⊕ Glenwood, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; died in the Edge Hospital, Troy, Oct. 29, aged 81.

Wendell, Thomas T., Lexington, Ky.; Meharry Medical College, Nashville, Tenn., 1900; also a graduate in pharmacy; for many years affiliated with Eastern State Hospital, where the Wendell building was named and dedicated in his honor; served on the staff of St. Joseph Hospital; died Oct. 4, aged 76, of cerebral hemorrhage.

Wiland, Louis, Erie, Pa.; Long Island College Hospital, Brooklyn, 1908; one of the original staff members of Beth El Hospital in Brooklyn, where he was an associate in medicine for many years; died Nov. 2, aged 66, of coronary thrombosis.

Wilson, William ⊕ Chicago; Loyola University School of Medicine, Chicago, 1916; affiliated with West Suburban Hospital in Oak Park, Ill., where he died Oct. 3, aged 63, of cerebral hemorrhage and hypertension.

Wirsig, Arnold Oswald ⊕ Shenandoah, Iowa; Drake University College of Medicine, Des Moines, 1912; died in the Hand Community Hospital Aug. 22, aged 69, of coronary thrombosis.

Wolff, Thomas Conrad ⊕ Baltimore; McGill University Faculty of Medicine, Montreal, Canada, 1917; associate professor of medicine at the University of Maryland School of Medicine and College of Physicians and Surgeons; died Aug. 25, aged 62.

Wood, George Harden ⊕ Batesville, Miss.; University of Louisville (Ky.) Medical Department, 1891; for many years served as county health officer and on the school board; local surgeon for the Illinois Central Railroad; died Sept. 27, aged 87, of cardiac failure.

Woods, Arthur Daniel ⊕ State Center, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; member of the American Academy of General Practice; member of the House of Delegates of the American Medical Association in 1938 and 1940-1953; for many years member of the state board of medical examiners; affiliated with Evangelical Deaconess Home and Hospital and St. Thomas Mercy Hospital in Marshalltown; died in Billings, Mont., Aug. 17, aged 72, of coronary occlusion.

Wylie, John Thomas, Dallas, Texas; Baylor University College of Medicine, Dallas, 1928; served during World War II; died Sept. 13, aged 50, of coronary occlusion.

Yeo, Gordon Hurst ⊕ Big Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; served during World War I; affiliated with Community Hospital, where he died Sept. 15, aged 66, of coronary thrombosis.

Young, Albert Frederick ⊕ Milwaukee; Rush Medical College, Chicago, 1894; assistant clinical professor of psychiatry emeritus at Marquette University School of Medicine; past president of the Milwaukee Neuropsychiatric Society; for 22 years superintendent of the Milwaukee County Hospital for the Insane; died in Columbia Hospital Aug. 24, aged 83, of coronary thrombosis.

Zimmerman, Amelia, La Porte, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1904; died in Waterford Aug. 6, aged 86, of arteriosclerosis and hypertension.

Zimmerman, Henry Samuel ⊕ Cameron, Ill.; Northwestern University Medical School, Chicago, 1896; served on the staffs of Monmouth (Ill.) Hospital and Galesburg Cottage and St. Mary's hospitals in Galesburg; died Nov. 7, aged 82, of angina pectoris.

GOVERNMENT SERVICES

ARMY

46th Surgical Hospital in Korea.—With the cessation of combat casualties, the 46th Army Surgical Hospital now operates on a semipeacetime status, while remaining constantly combat ready at the same time. The preoperative section of the hospital is now filled with beds. Sick call, of secondary importance when shooting was in progress four months ago, now handles thousands of patients a month. In surgery, where doctors worked on a 24 hour basis during hostilities, doctors now concentrate on routine surgery of a voluntary nature. In the medical section, usually filled to capacity, soldiers are receiving some of the best care in Korea. Movies and increased Red Cross facilities make life happier for patients at the hospital. The x-ray machines are being operated from dawn to dark. The neurosurgical section is active, since the 46th Army Surgical Hospital is one of only two Army surgical hospitals in Korea with equipment for such operations. Should war break out again, the hospital is prepared to handle any emergency that might arise, and it is just as mobile now as it was during combat. All medicaments and equipment are packed in open boxes, ready to be closed up and moved out, if necessary, at a moment's notice. Several practice moves have already been made successfully. Moving is commonplace at the 46th Army Surgical Hospital, which was the first Army surgical hospital to arrive in Korea in September, 1950.

NAVY

New Type of Reserve Unit.—A new type reserve unit for naval reserve doctors and other members of the medical profession is being organized in Chicago, Rear Adm. Francis P. Old, commandant, ninth naval district, announced. The unit, to be called Naval Reserve Surface Division (Medical) 9-240, will meet at Veteran's Research Hospital, newly completed skyscraper medical center, near the downtown campus of Northwestern University.

Doctors, medical specialists, veteran Navy hospital corpsmen, and administrative personnel are eligible to belong to this unit, which provides one day's pay for each drill attended. There are 48 scheduled drills per year. This is the first time Navy medical reservists have been able to join a paid reserve unit with regularly scheduled drill periods and definite curriculums for its participants.

The Chicago Naval Reserve Medical Surface Division is one of five established in a test program. Other units have been set up in Boston, New York, Charleston, S. C., and San Francisco. If these units prove successful, the program will be extended to other major cities of the country. Officers eligible for the Chicago Naval Reserve medical unit must be members of the Navy's medical corps and its medical specialist branch. They must be in the grades from lieutenant (junior grade) through commander, or enlisted personnel, including hospitalmen, yeomen, personnel men, and storekeepers. Officers and men of Chicago and its suburbs interested in affiliation with the Naval Reserve Medical Surface Division should call Capt. Fred Fluegel, U. S. N., Commanding Officer, Naval Reserve Training Center, foot of Randolph Street. His phone number is CEntral 6-6828.

Personal.—Rear Adm. Lamont Pugh, Surgeon General, was elected to the board of governors at the recent Clinical Congress of the American College of Surgeons. He will serve through the 1956 annual meeting.

AIR FORCE

New Chief of Preventive Medicine Division.—Col. Theodore C. Bedwell Jr. (MC) has assumed duties as chief of the preventive medicine division, Office of the Air Force Surgeon General, Washington, D. C. Colonel Bedwell was staff surgeon for the 5th Air Force in Japan and went to Korea with the advanced headquarters at the beginning of the conflict. He is certified by the American Board of Preventive Medicine.

Colonel Bedwell attended the Air War College, Maxwell Air Force Base, Alabama, and served in the Department of Defense on the staff of the Assistant Secretary (health and medical), prior to his present assignment. He succeeds Col. Fratis L. Duff, who is now commandant of Gunter Branch, USAF School of Aviation Medicine, Gunter Air Force Base, Alabama.

Medical Officer Receives Award.—Major Solomon E. Lifton (MC) has been awarded the Commendation Ribbon with metal pendant. He was commended for meritorious service during May 15, 1952, to Nov. 30, 1952, as command surgeon to the commander of Joint Task Force 132, which conducted nuclear and thermonuclear tests in conjunction with the Atomic Energy Commission at the Eniwetok Proving Grounds. He is rated as a flight surgeon and is presently assigned to the preventive medicine division in the Office of the Air Force Surgeon General.

VETERANS ADMINISTRATION

Residencies Available.—Vacancies are available for residents in internal medicine, pulmonary diseases, and general surgery at the VA Hospital, Albuquerque, N. Mex. The residency training program is sponsored by the University of Colorado School of Medicine. The residencies in internal medicine and general surgery are approved for three years and the residency in pulmonary diseases for one year. Salaries range from $2,640 to $3,300 per annum. There are also vacancies for full-time physicians on the chest service. For information, write to the Manager, VA Hospital, Albuquerque, N. Mex.

MISCELLANEOUS

White House Conference on Highway Safety.—President Eisenhower has called a White House conference on highway safety for Feb. 17-19, 1954, in Washington, D. C. Rear Adm. Harold B. Miller, U. S. N., retired, has been named director of the conference and Secretary of Commerce Sinclair Weeks will serve as general chairman. Admiral Miller was formerly director of public information for the U. S. Navy and now is head of the department of public information of the American Petroleum Institute. He said that the highway safety movement "is certainly one of our greatest and most urgent humanitarian challenges. Deaths on streets and highways this year will approach 40,000, a tragic and needless toll. Injuries will number nearly 1.5 million. As the President has pointed out, casualties in motor traffic in just one year exceed total American casualties for the whole Korean War." The February conference will bring to Washington outstanding representatives of business, agriculture, labor, women's groups, public officials, community, religious and national organizations, and the media of public information. Secretary Weeks said, "There is no mystery about what ought to be done, in every town and every state, to curtail the traffic accident toll. What's lacking is effective leadership, local leadership, to put this great humanitarian crusade into organized action. The President hopes that this conference will stimulate and encourage that kind of leadership in all parts of the nation."

FOREIGN LETTERS

ITALY

International Symposium on Cortisone.—An international symposium on cortisone was held in September at the Milan Technical Museum, where all the mechanical and technical drawings of Leonardo da Vinci are housed. The international symposium on vitamins had been held in the same place some months before (*J. A. M. A.* 152:1453 [Aug. 8] 1953). Prof. L. Villa, director of the medical clinic University of Milan, was the chairman. Among the foreign representatives were C. Levi Pirani, University of Illinois, Chicago, B. E. Lowenstein and Chambers, University of Miami and Cancer Institute of Miami, Fla., A. Gibson, Rahway (N. J.), A. Celestino da Costa, University of Lisbon, M. P. Stack Dunne, Cambridge University (Great Britain), P. Leroy, Paris Collège de France, F. Coste and F. Delbarre, Paris faculty of medicine and Cochin Hospital, R. Luft and B. Sjögren, Serafimerlasarett of Stockholm, E. Martin and G. Majno, Geneva medical polyclinic, W. S. Copeman, London Middlesex Hospital, K. Bröchner-Mortensen, University of Copenhagen, and J. Roskam and H. van Cauwenberg, medical clinic, University of Bavaria. Among the Italian participants were C. Cavallero, G. Bossa, T. Lucherini, E. Cecchi, G. Sala, C. B. Ballabio, R. Scalabrino, M. Rossanda, T. Galli, A. Marmont, A. Lunedei, E. Trabucchi, A. Rebecchi, and F. Ceresa.

The first part of the symposium dealt with the biology of cortisone and the adrenal cortex. It is well known that the adrenal needs vitamin C to produce its corticoids, especially hydrocortisone (compound F). The gland satisfies this need by withdrawing vitamin C from the circulating blood or the cellular tissues in which it is present or by pouring suddenly its reserve into the cortex. The question arises as to how the organism elaborates its own natural vitamin C. During the last months the studies of some English scientists—Isherwood, Mapson, and others—have indicated that plants and animals elaborate their own vitamin C by withdrawing it from sugars. The molecular structure of these sugars differs, however, from that of the sugars from which synthetic or artificial vitamin C is prepared. There is hope, therefore, that it may become possible to induce the human organism to build its own vitamin C by an endogenous or spontaneous way. The spontaneous production of cortisone would be greatly benefited by an endogenous formation of vitamin C. The other chemical element that the adrenal needs for its corticoids is cholesterol.

Prof. A. Celestino da Costa discussed the structure and function of the adrenal cortex. According to him, the concept that there are special zones in the adrenal for the secretion of the two types of cortical hormones—one exerting its activity mainly on the mineral metabolism and the other on the glycocorticoid metabolism—has not been confirmed. As for the three zones to which the three different secretions of the adrenal have been ascribed, da Costa is of the opinion that it is only a matter of three "stages" or three "phases" in which the adrenal cells find themselves, i. e., whether they are or not filled with products of secretion (first zone), or have been emptied (second zone). The third zone varies according to the animal species and depends on the form that the lipids and cholesterol derivatives assume in the cells of the adrenal cortex as in droplets and granulations.

C. Levi Pirani discussed ascorbic acid and the adrenal cortex. An increased stress involves a greater demand of the adrenals for ascorbic acid. Nevertheless it has been proved that the function of the adrenal cortex continues even when it has poured its own reserve of ascorbic acid. This evidently proves that it must supply itself with vitamin C from other sources and other nonspecific vitamin syntheses. From this arises the necessity to administer large quantities of ascorbic acid in case of a stress such as trauma or a burn that involves greater work for the adrenals.

B. E. Lowenstein discussed the effects of cortisone on the capillary circulation. Every "stress" has repercussions on the innervation of the arterioles and metarterioles that, because of the spasm, transmit the effects to the capillaries. Cortisone prevents many of these neurocirculatory disturbances.

C. Cavallero reported on cortisone and infections. He asserted that cortisone encourages the infection not because it alters the immunization system (gamma globulin) but because it slows down some activities of the cellular tissues. These activities are connected with the functions of the mesenchyma (histiocytes, plasma cells, mast cells, and fibroblasts). In other words, the infections are encouraged by cortisone not because this influences the antibodies system but because it exerts its fibrolytic, antihyaluronidase, and antirheumatic action. Although this action is beneficial from the standpoint of rheumatism, it attenuates at the same time the defense of the cellular tissues against the infecting germs.

M. Stack Dunne said that the concept of the adrenal cortex being controlled only by the hypophysis and one hormone, i. e., corticotropin, should be modified. He is of the opinion that "pure" preparations of corticotropin are rather a complex of other substances as well as the true and authentic corticotropin hormone. There could be, in other words, within the corticotropin itself a "family" of various polypeptides with a variety of actions and stimulations on the adrenal cortex.

The second part of the symposium dealt with the metabolic effects of cortisone. F. Coste discussed the hormonal secretions of rheumatic patients, G. Bossa the metabolism of carbohydrates, R. Luft comparative metabolic effects of cortisone, corticotropin, and desoxycorticosterone, Lucherini the interferences between cortisone and somatotropic hormone, Martin cortisone and bone tissue, and Sala the influence of cortisone on water and electrolytes metabolism in man.

The third part of the symposium dealt with the clinical effects of cortisone. The reports of W. S. C. Copeman made this the most interesting part of the convention. He concluded that rheumatic disease reappears as soon as cortisone therapy is interrupted no matter what doses and what routes of administration have been used. Ballabio, who was the first Italian to report on the clinical use of cortisone in Italy, emphasized the action of the drug in rheumatic carditis.

Scalabrino is so enthusiastic about cortisone in treatment of rheumatic disease that he censured the salicylic therapies that have been used until recently all over the world. But Roskam refuted Scalabrino's statements and said that the salicylates, mainly sodium salicylate and aspirin, should not be abandoned but their true effects should be evaluated, especially in view of the discovery of cortisone. It was proved in fact that they produce, even if in small quantities, corticotropin because they stimulate the hypothalamus, diencephalon, hypophysis, and adrenals. Aspirin and cortisone can be administered concurrently without fear of therapeutic antagonism.

The personal experience of Maramont (Italy) with cortisone and corticotropin in acute lupus erythematosus disseminatus is important. The severe symptoms generally regress but they do reappear when resistance to the drug has developed. Nonetheless the treatment is always useful. Cortisone and corticotropin therapy aggravate severely the condition of patients in whom the disease is mild but the renal function is impaired.

Robecchi, from Turin, reported on the first 110 patients (119 joints, 305 injections) he treated with cortisone. He obtained the best effects in patients with periarthritis of the shoulder. The results varied in patients with chronic poly-

arthritis. However temporary the surprising improvements may be, cortisone can be combined with complementary treatments of polyarthritis that potentiate the effects of cortisone. All the patients tolerated the therapy very well.

Androgen Therapy in Gynecology.—Prof. Angelo Migliavacca, University of Milan gynecologic clinic, read a paper on the modern evolution of androgen therapy in gynecology before the Swiss Gynecological Society in Bern. He recalled the history of the first application of testicular extracts in gynecology and discussed the importance of their dosage in relation to various phenomena that are linked to the complex sexual hormonal balance. Many gynecologic as well as systemic disturbances in women may be treated with androgenic steroids. Often a clear distinction between these disturbances is not possible. Sometimes androgens given for a gynecologic disturbance may produce unwanted side-reactions, as in metrorrhagia. While they have a hemostatic effect on the genital organs, they may also cause hypertrichosis. Androgens given for nephrosis may cause irregularity and diminution of the menses, sometimes to the point of amenorrhea. It seems, however, that the general symptoms appear only when massive doses of hormones are used.

Professor Migliavacca believes that, although the mechanism of action of the androgens is difficult to interpret in some cases, in others they are clear, as in the case of inhibition of lactation through the inhibitory action of the androgens on the hypophysis. The therapeutic effect of androgens on some disturbances of the breast (mastodynia, fibrocystic mastopathy, and the so-called premenstrual tension) may be due to a progesterone-like action. It is less easy to explain the metabolic effects of the androgens and especially their anabolic effect. This is one of the most characteristic side-effects and because it is common to the adrenal steroids, one may be led to suspect that it is a metabolic repercussion of stress.

The androgens favorably influence the assimilation of proteins and diminish the excretion of nitrogen. These actions in cases of negative nitrogen equilibrium due to excess loss of nitrogen may explain the favorable "nephrotropic" effect. It is difficult to advance a hypothesis to explain the influence of androgens on calcium metabolism, which becomes manifest also through a stimulation of the parathyroids, with production of an abnormally great rise of blood calcium. It is likewise difficult to explain their effect against carcinoma of the breast, especially if it is metastatic. It is a therapy that slows down the evolution of the tumor and metastasis, especially the metastases to the bones. According to Professor Migliavacca, it is probably an indirect action of the massive doses of androgens on the hypophysis, of which not only the gonadotropic secretion would be inhibited but also that of the somatotropic hormone, the so-called hormone of growth, which may perhaps be responsible for the growth of the tumor.

The mechanism of action of androgens on the nervous system and the psyche in cases of sexual frigidity, depressive psychosis, and other such states has not been clarified. Frigidity in women is mainly due to psychogenic factors; the androgens sensitize the diencephalic vegetative nervous system, one of the most sensitive peripheral receptors of the effect of androgens. As for the improvement of depressive psychic states and the reestablishment of balance in neurovegetative dystonias that often follow androgen therapy, they seem to be due to an indirect nonspecific action of the androgen, possibly through the hypophyseal-hypothalamic system. Analogous effects have been obtained with massive doses of desoxycorticosterone and other steroids. This hypothesis seems to be confirmed by a comparison between the effects that can be obtained with androgen therapy and those obtained with electroshock therapy in these states. The balancing action of the androgens on the vegetative nervous system and the tonic general and dynamogenic action can be explained partly by the anabolic, fattening effect of the androgens.

In recent years androgens have been combined with other sexual hormones for some conditions, and the latest achievements of biological chemistry have made available to clinicians other synthetic steroid substances with actions that are analogous to those of the androgens. The combination of androgens and estrogens, in proper weight ratio, is used especially to treat neurovegetative disturbances of the climacteric, because it has proved more valuable than treatment with estrogens alone. The quicker action of the combined therapy is ascribed to the fact that the two hormones inhibit synergistically the production of follicle-stimulating-hormone by the anterior lobe of the hypophysis. This combined therapy is also indicated after surgical or radiological castration to neutralize or modify the therapeutic activity of estrogens alone according to a method that was once widely used.

Professor Migliavacca believes that a definitive statement about the combination of sexual steroids in therapy is not yet possible, although clinical experience with the use of the various formulas worked out by the pharmacological industry is rapidly being accumulated. The introduction of hormonal steroids with action resembling that of androgens in gynecological therapy has made it possible to exploit therapeutically some useful pharmacodynamic activities of these preparations, even though they do not possess all the actions that are characteristic of testosterone.

Diagnosis of Hyperadrenocorticalism.—Professor Ceresa, Turin, read a paper on the test and spectrophotometric curves of Allen in the diagnosis of hyperadrenocorticalism before the medical and surgical society of Pisa on Feb. 21, 1953. He studied the spectrophotometric absorption curves of the urine of seven women. Cushing's syndrome was present in three of them, virilism in one, and hypertrichosis with increased androgenuria in three. In one patient with Cushing's syndrome in whom there was a tumor of the adrenal cortex, the spectrophotometric curve indicated maximal absorption, especially in the region of 600 mμ. In other words, it behaved in a way that, according to American authors, is typical of functioning adrenal tumors. Gardner and Migeon assert that curves with the aforementioned characteristics occur only when the tumor produces clinical virilism. In this instance the curve was quite typical, despite the fact that the tumor was accompanied by findings typical of Cushing's syndrome and although there was also a marked tendency to virilism.

In the other two patients with Cushing's syndrome, the curve did not present the point of absorption in the region of 600 mμ, which is characteristic of a tumor of the cortex. Radiological investigation with pneumoperitoneum in one case and surgical exploration in the other revealed that a tumor was not present. The curve behaved this way in two patients with hypertrichosis and increased androgenuria. Pneumonography of the adrenals revealed that the volume and form of the glands were normal. In the third patient with hypertrichosis and increased androgenuria, the spectrophotometric absorption curve revealed a slight point at 600 mμ. This disappeared after cortisone therapy. According to Gardner and Migeon, the presence of an adrenal tumor may be confirmed by this finding.

The curve in the patient with virilism was identical to that which Gardner and Migeon describe as typical of hyperplasia of the adrenal cortex not due to a tumor. It was characterized by a slight absorption point at 600 mμ, and this point was slightly smaller than that of normal absorption curves. Unlike American reports, the absorption at 600 mμ did not change after cortisone therapy.

At the same meeting Drs. Ceresa, Lacroix, and Randone reported that they studied roentgenographically after retropneumoperitoneum the adrenal glands of 16 patients with hyperadrenocorticalism and of 7 normal persons. Comparing the results obtained with the standard roentgenography and those obtained with body section roentgenography, they observed that some adrenals can be visualized with the body section technique that could not be with standard roentgenography. It is necessary, however, to know how to interpret the findings in order to avoid mistaking some small adipose masses or renal cysts for adrenal glands.

LONDON

General Practitioners' Records.—A recently published report on the records of general practitioners by Dr. W. P. D. Logan, chief medical statistician, General Register Office, is based on an analysis of the clinical records of eight practices during the period, April, 1951, through March, 1952. The importance of this report lies not so much in its findings but in the fact that it represents the first serious attempt to make use of the mass of clinical data that is to be found in the records of general practitioners but that, in the past, has been lost to posterity with their death or retirement. The primary objective of this survey was to determine to what extent the clinical records of general practitioners could be used as a source of general morbidity statistics and to study the problems associated with this use of these records.

The eight practices chosen were selected because of their location and character and not because of the special interest that the practitioners had evinced in keeping records. No uniform method of record keeping was imposed. Each practitioner was encouraged to choose his own system. The data from each practice were sent to the General Register Office, where they were sorted and analyzed. Only the records of National Health Service patients were used. The practices were representative of both rural and urban practice and ranged in size from 7,700 patients in Liverpool to 1,900 in Kent and Sussex. Altogether, 27,365 patients were included in the survey. Measles, which headed the infectious diseases in the number of consultations for which it was responsible, had a patient-consultation rate of 39.2 per 1,000 practice population. It was closely followed by respiratory tuberculosis, with a rate of 37. There was not a single consultation for poliomyelitis or infective encephalitis and only three (representing two patients) for diphtheria—all in one practice. Asthma had a rate of 52.3; diabetes, a rate of 3.4; and pernicious anemia, a rate of 0.4; whereas the rate for other anemias was 11.4; psychoneurotic disorder, 109.6; benign hypertension, 73; the common cold, 252.9; and bronchitis, 328.9. About one patient in every hundred had a consultation with his doctor for some nonmedical reason during the course of the year. Whether they were for general advice, such as the family doctor of the old days often gave, or for other reasons was not indicated. The seasonal variations were interesting. Although consultations for the common cold, influenza, pneumonia, otitis media, and bronchitis increased during the winter quarter, those for acute tonsillitis showed no seasonal variation. Consultations for the various forms of arthritis varied little, but there was a small increase during the winter months in the number of those for muscular rheumatism.

Three out of every five consultations were with female patients, but this was partly accounted for by the fact that there were more females than males in the practice population. There were some interesting sex differences in the incidence of different disorders. Thyrotoxicosis was diagnosed in 1 male and 25 females; myxedema, in 4 males and 51 females; migraine in 50 males and 123 females; benign hypertension in 82 males and 402 females; and, of the patients with symptomatic diagnoses, those labeled debility or headache were mainly females, 15 to 64 years old. Just over two-thirds of all the consultations were in the office, and the rest were home visits. The total consultation rates per 100 practice population for males aged 15 to 44 were lower than in those under 15 or over 44 years of age, but for females there was a steady increase in rates from childhood upwards. Except in childhood, the rates for females at each age were higher than those for males. The consultation rates showed marked differences in individual practices, ranging from an average of 2.9 to 4.7 consultations per patient per year. There was no evidence that consultations are generally more numerous in urban than in rural practices. In all practices combined, there were 3,090 outpatient referrals to hospital and 563 inpatient referrals, representing 3 per 100 and 0.5 per 100 total consultations, respectively.

It was concluded "that a small group of practitioners have been able, without exceptional difficulty and without being specially selected for the purpose, to keep records of all their work. . . . It has also been shown that these records have been suitable for statistical analysis, and that this analysis has made available a considerable amount of information about the nature of general practice and about the prevalence in the population of the kinds of illness that come to the notice of general practitioners. . . . Although the keeping of complete and continuous records has been a task making considerable demands upon the practitioners, it was found that once a satisfactory routine method had been adopted it could be carried on without much difficulty, even during periods of increased sickness prevalence." On the other hand, the warning is given "to practitioners who propose to embark upon a comprehensive analysis of their own records that the processes of statistical analysis may prove much more burdensome than the record-keeping itself." This definite opinion was expressed: "There can be little doubt that these records potentially constitute one of the most valuable sources of information on morbidity." In a commendatory foreword, Sir John Charles, chief medical officer of the Ministry of Health, expressed this view: "It may be that the College of General Practitioners, with its expressed interest in research, will be able to enlarge the sphere of operations and so help to add fresh chapters to these careful chronicles."

Causes of Blindness in England.—A report, entitled "The Causes of Blindness in England 1948-1950," by Prof. Arnold Sorsby, has just been published by the Ministry of Health. It is based on an analysis of over 19,000 blindness registration certificates, representing about 90% of the total newly registered blind in England during 1948, 1949, and 1950. Of the blind population registered in these years, 5.9% were totally blind, having no perception of light, and 17.1% had perception of light only. Practically 90% of the registered blind were over the age of 50 at the time of registration. Only 1.6% were in the age group from birth to 4 years old, but this low percentage does not necessarily prove a correspondingly low incidence of blindness, since many blind infants may not have been registered until later in life. A typical geriatric note is struck in the comment that 61.2% of the blind population were over 70, although this group included only 6.8% of the estimated general population in 1951.

Cataract, senile macular degeneration, and glaucoma accounted for practically 60% of all causes of blindness; myopia and the congenital and abiotrophic anomalies, for 16.5%; diabetes, for 4.3%; syphilis (acquired and congenital), for 1.2%; and ophthalmia neonatorum, diseases of the central nervous system, and trauma, for less than 1% of cases. In the age group from birth to 4 years old, 77.7% of all blindness was caused by congenital defects. In the group 5 to 14 years old, congenital anomalies accounted for 57.5% of all causes, but abiotrophic anomalies, myopia, diseases of the central nervous system, intracranial tumors, and optic atrophy of unknown origin contributed 5% each. In the group 15 to 29 years old, congenital anomalies accounted for 33.2%, the abiotrophic anomalies for 16.3%; myopia, for 6.9%; and trauma, iritis and congenital syphilis, optic atrophy of unknown origin, and intracranial tumors, for about 5% each. In the group 50 to 69 years old, cataract accounted for 20.3%; glaucoma, for 14.7%; myopia, for 15.7%; and diabetes, for 8.4%. In those over 70, cataract caused 41.1%; senile macular degeneration, 22.9%; glaucoma, 15.8%; and myopia, 10.2%.

In about 31.3% of all patients registered as blind from cataract the condition was regarded as remediable; in 31.9% it was regarded as remediable, except that operation was inadvisable because of poor general health; the prognosis was doubtful in 28.4%; and in 8.5% the condition was considered irremediable. Eighty per cent of those registered as blind from cataract had received no treatment. In the case of glaucoma, surgical treatment had failed in 57.8%; in 76% of cases treatment had been incomplete; and in 34.6% there had been no treatment. The report comments: "The . . . proportion of glaucoma patients who are blind in spite of operation . . . indicate that there is room for better organization of facilities for the early diagnosis of glaucoma. In these returns 31.9 per cent. of cataract patients are shown as amenable to treatment as far as the eye is concerned, but unfit for operation because of their poor general health. If these findings are taken on their face value, the problem of cataract becomes part of the larger issue of geriatrics, but it is possible that many patients recorded as unfit for operation by some examiners would in fact be urged to undergo treatment by others, as would perhaps some of the 28.4 per cent. returned as with prognosis 'doubtful.' These considerations emphasize that a decision as to a patient's suitability to undergo a cataract operation calls for the judgment of an operating surgeon. Were those blind from cataract a relatively small proportion of the total number of those registered annually as blind the problem might not appear significant. But cataract contributes each year, about 2,500 to 3,000 blind, some 80 per cent. of whom have not had any treatment.

"In glaucoma, time lost spells irretrievable loss of sight. . . . Some 1,200 to 1,500 individuals blind from glaucoma are registered annually, and hundreds . . . suffer from serious visual disability caused by the affection. If any reduction in these numbers is to be achieved more effective means for early diagnosis will have to be established. Though there are still many difficulties, early diagnosis is a not impossible objective today. It may fairly be asked whether the present organization of eye hospitals is adequate to cope with the time-consuming special methods that are called for. The establishment of special glaucoma clinics at some centers is a recognition by some hospital authorities of the special difficulties involved. That many such centers are needed, and that special facilities should be granted to them, would seem obvious."

In reviewing the figures for England and Wales as a whole, it is pointed out that in March, 1948, the number of registered blind was 77,390, compared with 71,875 in March, 1938. The annual increase rose from 7,586 in 1948 to 11,155 in 1951. This was attributed to the natural increase in the population, and the mode of registration as a result of a greater readiness on the part of examining surgeons to certify the patients with borderline cases as blind. There appears to have been an actual increase in the number of blind children. In the case of children 5 to 14 years old, the marked decline observed between 1923 and 1942 is no longer continuing. The rate per 100,000 was 21.6 in 1948 and 21.2 in 1951. The number of new registrations in the age group 1 to 4 years old, has risen from 45 per year in 1937 to 136 in 1951. More effective registration may account for part of this increase. In the case of infants under one year of age registrations have risen from 11 in 1937 to 44 in 1951. "As the number of infants in the general population is declining, the increase in the number of registrations suggests either markedly more efficient registration, or an actual increase in the number of blind infants—as is likely from the emergence in recent years or retrolental fibroplasia as a new blinding affection in infants." The proportion of blind persons over 70 years old has risen steadily from 22.4% in 1923 to 47.4% in 1951.

Medical Defense Union.—At the annual meeting of the Medical Defense Union on Sept. 15, Dr. S. Cochrane Shanks, the president, referred to the rising tide of litigation. Perhaps the most potent cause for this is that the hospitals are now state institutions and so are fair game. In the past, a patient might hesitate to sue a voluntary hospital or a physician who gave his services free. Today it is the Treasury that pays, and the physician, too, now that he is salaried. Another powerful encouragement to the discontented patient is the Legal Aid and Advice Act of 1949, under which litigants may receive free legal assistance in their actions against hospitals and doctors. As Dr. Shanks so aptly puts it: "In this welfare social estate of ours a patient may be provided with free medical treatment by the State, and may subsequently, at the State's expense, sue the State for negligence. He will, if successful in his action, receive compensation from the State. He will, even if unsuccessful, have his legal expenses paid by the State and, being a poor person under the Act, will not be called upon to pay the legal expenses incurred by the State in rebutting his unsuccessful and sometimes frivolous suit. Was even Dr. Faustus submitted to greater temptation?"

Two other factors add impetus to this flood. The first is the example of the compensation paid to injured persons under the Road Traffic Act. In road traffic accidents it is up to the defendant to prove that he was not negligent, and there is in the minds of the public—and sometimes even in that of the courts—an unfortunate carry-over into medicolegal cases. "I have not been cured; I must therefore receive compensation" is becoming almost a slogan. Finally there is the attitude of the less intelligent public press. Negligence, real or alleged, on the part of the physician is news, perhaps headline news. By the time the negligence has been disproved to the court's satisfaction the story is dead and other sensations have taken its place, but the impression left with the litigious patient is obvious.

The Medical Defense Union's council, through its representatives, has continued joint negotiations with the Ministry with the object of defending unwarranted actions together and of settling just claims by a defendant in amicable agreement. Dr. Shanks believes that agreement may soon be reached between the three defense societies, the British Medical Association, and the Ministry.

NORWAY

Nephropathia Epidemica.—Recent Scandinavian publications concerned with nephropathia epidemica suggest that this may be a disease that is by no means rare. The credit for the identification of this condition as a disease sui generis is largely due to Scandinavian workers. In the autumn of 1933, Zetterholm observed seven cases in a Swedish hospital. In the same year and independently of Zetterholm, Myhrman gave an account of seven similar cases, and in 1945 he suggested the application of the term nephropathia epidemica to this disease. He has subsequently collected nine other cases also observed in Sweden. Meanwhile similar cases were beginning to be diagnosed in Norway. In 1949, Knutrud reported three cases. In 1950, Muri reported 14 cases observed in the Opland County Hospital at Lillehammer in the period September-November, 1949. He reported another case, the details of which are published in the *Journal of the Oslo City Hospitals,* September, 1953.

The two most characteristic features of this disease are its epidemic character and changes found in the urine. The clinical findings are remarkably uniform, judging by the cases hitherto recorded. After prodromal symptoms with general malaise lasting a few days, the patient becomes ill with shivering, fever, violent headache, and pain in the trunk and limbs. This pain tends to bring the patient to the hospital with a diagnosis of "acute abdomen," Weil's disease, influenza, pleurisy, or pneumonia. In Muri's cases, the specific gravity of the urine was high during the first few days, but from about the fifth day hyposthenuria or isosthenuria developed. Proteinuria disappeared about the 10th day, but the ability of the kidneys to concentrate urine was impaired for several weeks. Blood urea was temporarily increased in most cases. In the absence of edema and a high blood pressure, the clinical findings can be distinguished from those of acute nephritis. After Muri gave an account of epidemic nephropathy at a meeting of a local medical society, five new cases were correctly diagnosed before admission to the hospital. This shows how helpful it is for a given disease to be in the mind of the physician confronted by a new and acute condition.

Dextran.—On Sept. 29 a series of lectures on dextran was given in Oslo by Professor Stacey of Birmingham University in England, Dr. Jon Jonsen, and Dr. Ivar Lund. In Dr. Lund's investigations, 29 healthy fasting subjects were given infusions of 1,000 ml. of eight different preparations of dextran. The rectal temperature and pulse rate were recorded every half hour. None of the volunteers had ever presented manifestations of any allergic disease, but 15 of them reacted to the infusions in various ways, such as flushing of the face and neck and, in the severer cases, extensive urticaria lasting for some hours. Headache and malaise, slight fever, nausea, and vomiting occurred frequently, and two of the volunteers fainted on rising. A certain relationship was noted between the degree of the reactions and the length of the interval between these experiments and the last immunization against typhoid and paratyphoid A and B. Some of the preparations caused allergic reactions in all the typhoid A and B immunized volunteers. Dr. Lund has published some of his findings in the *Journal of the Oslo City Hospitals* (no. 1, 7, and 8, 1953), and he has concluded that, among the various plasma expanders, dextran is the most promising, in spite of the reactions caused by it. The ideal plasma expander is yet to be produced.

Capillary Microscopy of Skin Diseases.—At the dermatological department of the Rikshospital in Oslo, Dr. Oscar Gilje recently carried out capillary microscopy of various skin diseases in the hope of finding an aid to their differential diagnosis. In patients with eczema, he found that the capillary picture varied greatly with the clinical findings. In lupus erythematosus, the most striking feature of the capillaries was a round or oval formation representing the follicular hyperkeratosis and the short, thick, usually horizontal, loops or arcs of vessels. Ichthyosis presented an entirely different picture, with slender, long, narrow capillaries and with no particular differentiation of the arterial and venous branches. In some of the thin capillary loops, it was possible to follow the blood stream that presented the appearance of beads on a string. In dermatomyositis also, the capillary picture seemed to be characteristic. Dr. Gilje believes that capillary microscopic examinations of the skin can reveal features pathognomonic of some skin diseases. He suggests that this test may throw light not only on the diagnosis but also on the pathogenesis of certain skin diseases. Several of the pictures he took are reproduced in *Acta dermato-venereologica* (33:303, 1953).

Death of Dr. Trygve Braaty.—The unexpected death of the psychiatrist, Trygve Braaty, at the age of 49, has robbed Norway of a singularly forceful personality. Dr. Braaty qualified as a doctor in 1929, and after some experience in general practice he held various appointments in general as well as in psychiatric hospitals. In 1936, his thesis for the degree of doctor of medicine was entitled "Men Between the Ages of 15 and 25." His love of challenging orthodoxy came out in full in this thesis and aroused some opposition. In 1945, he was put in charge of the psychiatric department of Ullevaal Hospital, but he retired from it at the end of 1952 in order to emphasize his disapproval of the mechanization of hospital practice. With his gifts as a speaker and writer, he was successfully eloquent in defending the rights of the patient who becomes a mere case in the complicated machinery of a modern hospital. His latest work, "The Patient and the Doctor," became a best seller in Norway by virtue of its revolutionary spirit.

TURKEY

Neuroblastoma of the Adrenal Medulla.—Dr. Kenan Aker, chief pediatrician of Istanbul-Shishli Children's Hospital reported in *Anadolu Klinigi* a case of neuroblastoma of the adrenal medulla. The patient, a 5-year-old boy, had had intermittent fever for three months. He often vomited, had pain in the back and legs and no appetite, and was weak and anemic. He had hard nodules under the chin and slight exophthalmus of the left eye. His abdomen was distended, and on the left side of his thorax a small mass was felt. His blood cell count revealed 3,640,000 red blood cells, 13,200 leukocytes, and 54% hemoglobin. He complained of pain in the joints and abdomen. There was an exostosis at his right fontanel and in the region of his left temporal bone and a softer exostosis, the size of a walnut, attached to this bone. Along his sternocleidomastoid many small lymph nodes were palpable; his abdomen was distended; and his liver was palpable 2 cm. below the costal margin and was firm. The exostosis gradually became more prominent, and another developed in the frontal region. Biopsy verified the diagnosis of neuroblastoma. Radiographic examination of his skull revealed widened diploë in front and back and seven exostoses of varying density. His liver had become palpable 7 cm. below the costal margin. His eyes protruded, and the pupils of both eyes were fixed. His pain increased, and his teeth fell out. At the end of three months his erythrocyte count was 1,290,000; his leukocyte count was 4,500; and his hemoglobin level was 40%. Symptomatic treatment and radiotherapy gave no relief, and the patient died after four months in the hospital and nine months after the onset. An autopsy verified the clinical diagnosis. The left adrenal gland was larger than a walnut, and section revealed a grey hard malignant tumor that had displaced the kidney downward. Around the para-aortal, abdominal, peripancreatic, mesenteric, perigastric, hepatic, and iliac arteries the lymph nodules were the size of lentils and walnuts. The liver and spleen were enlarged.

Thiosemicarbazone in Tuberculosis Therapy.—Thiosemicarbazone (Conteben), first used in 1947 in German clinics as an adjuvant in tuberculosis therapy has been used in Turkey since 1950. In *Dirim* Dr. Yakup Çelebi, medical director of Istanbul-Haydar Pasha Tuberculosis Hospital, reported on results obtained with this drug. Of 27 patients, 12 were given only thiosemicarbazone. In 7 of these there was clinical and radiological improvement; in 3 there was no improvement; in one there was marked improvement; and in one there was no change. Of the other 15 patients who were given thiosemicarbazone, streptomycin, and *p*-aminosalicylic acid, 12 showed clinical and radiological improvement; 2 showed slight improvement; and one was made worse. The ages of the patients ranged from 15 to 41 years. All had exudative tuberculosis in both lungs; several had cavities; a few had laryngeal tuberculosis; and all patients had positive tuberculin reactions. The initial dose of thiosemicarbazone was 0.05 gm., and this was gradually increased to 0.15 gm. A few patients had nausea, vomiting, and vertigo, and their therapy was interrupted for a few days. Side-effects necessitating the complete discontinuance of the treatment did not occur.

Thiosemicarbazone has proved effective in tuberculosis associated with empyema. As an adjuvant and following a pleural irrigation performed once or twice a week, thiosemicarbazone in the form of a suspension in 2.5 cc. of sterile glycerin or saline solution or in the form of a powder proved beneficial. In the patients who recovered, cavities and other lesions had healed; tubercle bacilli in the sputum had disappeared; the cough had decreased and was less productive; the appetite had improved; and there was a gain in weight.

Phytobezoar.—Dr. Tarik Temel, radiologist at Istanbul Cerrah Pasha Municipal Hospital, reported in *Klinik* an exceptional case of phytobezoar. Since 1914, when the late Prof. Hamdi Suad Aknar reported three cases of phytobezoar, 175 cases have been reported by Professors Kazim Ismail Gürkan, Perihan Çambel, Halid Ziya Konuralp, Dr. Hazim Bumin, Dr. Avni Aksel, and E. Çavushoglu. The phytobezoars were encountered in mountain shepherds, soldiers, or persons isolated because of war conditions or during a famine when they ate plants, wild fruit, and roots. Two months prior to admission while working in the forest, a 17-year-old farm boy had eaten many Trabzon dates (Diospyrus lotus), a wild fruit that grows profusely in the Black Sea forests. During those two months he had epigastric pain that had no relation to taking food. He was relieved by vomiting or when he took a sedative. The pain suddenly became violent, he vomited excessively, his temperature rose, and he was taken to the hospital. On admission he was weak and anemic; he had a temperature of 101 F and a pulse rate of 120. There was tenderness and rigidity of the epigastrium but no abdominal distention. The blood cell count revealed 1,600,000 red blood cells, 8,000 leukocytes, and 45% hemoglobin. The differential count was normal and the sedimentation rate was 63 mm. The patient was given cardiotherapy and antibiotics. After 10 days his temperature returned to normal, his epigastrium and hypochondrium became soft, and a large mobile soft abdominal mass was palpated. Radiographic examination revealed the stomach to be distended, and in the center was a large, irregular, sponge-like mass. After the patient had several blood transfusions, Prof. Dervish Manizade performed gastrotomy and removed the phytobezoar. It consisted of a brown vegetable mass of foul odor that contained many date seeds. It weighed 1,175 gm. and was 15 cm. long and 6 cm. wide. The patient's recovery was uneventful.

CORRESPONDENCE

SALT-POOR DIET AND JEWISH DIETARY LAWS

To the Editor:—A salt-poor diet prescribed in cases of hypertension or congestive heart failure causes difficulties when prescribed to a person strictly adherent to Jewish dietary laws. These laws demand, for the purpose of removing any traces of blood from the surface of the meat, that it be abundantly salted before use. To eat meat without this preparation creates a religious problem and a conflict for the observing Jewish patient. Such meat has indeed a much higher sodium content than similar unprocessed material. Some Jewish hospitals tried to avoid the problem by using ammonium chloride instead of salt. According to Jewish law, this or the substitution of sugar for salt is not permissible.

For a long time, I have used the following method to solve the difficulty. The patient was told that, after salting the meat in the religiously prescribed way, he should put it in water for one and a half or two hours and change the water two to three times during this time. It is also my procedure to allow patients on a salt-poor diet to eat only boiled (not fried or broiled) meat and not the soup. It has never been proved that boiled meat loses any of its essential nutrients or has a lower food value than broiled or fried meat. In an effort to determine the sodium content of salted and unsalted meat prepared in various ways, investigations were performed in the Food Research Laboratories, Inc., in Long Island City. Samples of the different materials were ashed by digestion with perchloric acid and hydrogen peroxide, the meat samples having been prepared before by grinding in a food chopper. Sodium determinations were made by means of the Beckman flame photometer. To find out whether there are typical differences in the sodium content of different types of meat, one part of each sample remained unsalted, "the untreated piece." It was compared with a part from the same sample salted according to the usual Jewish dietary laws, "the treated piece." The difference in sodium content was:

Cut	Moisture, %		Na, Mg./100 Gm.	
	Untreated	Treated	Untreated	Treated
Brisket end	61.6	61.0	69.0	284
Single chuck	64.1	64.1	42.4	222
Breast flank	56.2	55.8	52.6	195
Average	60.8	60.3	54.7	234

After these preliminary investigations the intended experiments could be started. On four pieces of raw beef, each weighing approximately 500 gm., the salting process was carried out equally in each piece in the following way. After soaking for one-half hour in sufficient cold water to cover them, the pieces of beef were placed on a tilted platform and were sprinkled by hand with coarse salt. In order to equal the usual kitchen procedure, the amounts of salt were not measured, and, therefore, not exactly the same amount was used for each piece. After standing for one hour after the salt was added, the pieces were rinsed under running tap water and drained. A small slice was then cut from each piece, and the four slices thus obtained were composited for analysis without further treatment. These pieces were sample 0 shown in the second table. One piece of beef was then covered with cold water, brought to a boil, and simmered until tender (about one and one-half hours). The broth in which this piece was cooked was discarded and the meat saved for analysis as sample 1. A second piece of beef was covered with cold water and allowed to soak for one-half hour. The water was then poured off and replaced with fresh water in which the meat was cooked as described for sample 1. About 700 to 1,000 ml. of broth remained after cooking in this case and also in samples 3 and 4 described. Both the meat and the broth were saved for analysis and identified as sample 2. The third piece of beef was soaked for one-half hour in three consecutive changes of cold water in quantities sufficient to cover the meat. The meat was then immersed in fresh cold water and cooked as above. The meat and broth were identified as sample 3. The fourth piece of beef was soaked for one-half hour in three consecutive changes of hot tap water (165 F). The meat was then cooked as described above. The meat and broth were identified as sample 4. Equal samples of the cooked meat were prepared after grinding. Aliquots of meat and broth were ashed with perchloric acid and hydrogen peroxide, and sodium determinations were made on the residue. The results obtained are shown in the second table.

Sample	Treatment	Na Found	
		Meat, Mg./100 Gm.	Broth, Mg./100 Ml.
0	Salted, unsoaked	390	...
1	0, cooked	75	...
2	0, single cold soak, cooked	63	122
3	0, triple cold soak, cooked	76	89
4	0, triple warm soak, cooked	58	22

One other experiment was performed. Since, in the average kitchen, the amount of salt put on the pieces of meat is taken haphazardly, a greater amount of salt was used for the treating process. A single piece of raw beef weighing about 5 lb. (2.3 kg.) was divided into three equal portions. An adequate part of each portion was removed and composited to form a control sample. One portion was boiled without addition of salt, and meat as well as broth was analyzed for the sodium content. The two remaining portions were salted, and a small slice of each was taken for study before cooking. One piece was boiled in water, and meat and broth were analyzed. The third piece was cut in two and broiled. The next table shows the results of this procedure.

Sample Analyzed	Na Found, Mg./100 Gm.
Raw, unsalted	64.9
Unsalted, boiled	34.6
Broth from unsalted, boiled meat	23.6
Raw, salted (treated)	705.0
Treated, boiled	334.0
Broth from treated, boiled meat	372.0
Treated, broiled	375.0

The data obtained prove first that the processing of raw meat according to Jewish dietary law increases the sodium content remarkably. From the second table it can be seen that, if salting is not excessive, cooking takes out practically all of the added sodium. The sodium content of the differently prepared specimens in the same table is very close to that found in meat not salted before cooking. This proves that the moderate amount of salt added goes into the soup in the cooking. It is justifiable, in a salt-poor diet, not to permit the patient to eat the soup if the meat was processed before in the ritual way and not to allow him to eat fried or broiled meat of this kind. It is clear, on the other hand, from the figures in the second table that soaking the salted meat in cold or warm water before cooking removes the salt sprinkled on the surface quite well, especially if that soaking is in warm water and the amount of salt is not excessive.

In the second experiment, the sodium content of the meat was much higher than in the first. This was probably due to the high amount of salt used. It can also be seen that when the salted meat was not soaked twice for half an hour its salt content remained high and boiling removed only a little more than half the salt content. It is interesting to note that broiling reduced the sodium content to a high degree, but not so much as boiling does. Apparently, a considerable amount of the salt put on the surface of the piece is carried away by the dripping fluid during broiling. It seems that if treated meat is to be used in a salt-poor diet, the cook should use a minimum of salt, allow the meat to stand only for the religiously permissible minimum of time, cook the meat in a generous amount of fluid and throw the broth away.

COUNCIL ON MEDICAL SERVICE

This is the seventh in the series of articles on Physicians Placement written by medical students from Northwestern University Medical School after visiting the states for the purpose of studying the program on the state level.

PLACEMENT OF PHYSICIANS IN TEXAS

STATE CONDITIONS IN GENERAL

In most areas the state of Texas is adequately supplied with physicians. Within its boundaries there is one physician for every 813 persons. This physician population ratio compares favorably with the national average of one physician to every 730 persons. But, because Texas has so many square miles of sparsely populated land, the larger proportion of the physicians are located in towns ranging from 1,000 to 25,000. Even in view of this, the acknowledged need for more physicians is in towns with populations less than 25,000. Geographically, the maldistribution of physicians can be pointed up by considering roughly the eastern and western portions of the state. The eastern half is well populated and has more than an adequate number of physicians in relation to population. The western half, including the Panhandle, is, in general, sparsely populated range land with fewer physicians in relation to population. Of the 254 counties in Texas, a survey in 1951 showed that 10 had no physician. All of the 10 counties were in the western part of the state. Of these 10, only one area indicated a population concentration sufficient to support a physician.

The attitude of the people toward travel affects the demand for medical care. In the western areas, persons will travel as much as 30 or even 50 miles without complaint to reach a physician. In the eastern areas with the greater concentration of people, patients prefer to have medical service located, so to speak, at their fingertips. There are, in Texas, a large number of privately owned hospitals. The staff of such a hospital is frequently closed, because the present staff owns the hospital. This situation sometimes discourages additional physicians from entering such areas, but the Hill-Burton program now offers some relief. Another factor complicating medical practice in some areas is the number of "cultists." They tend to gravitate toward the sparsely populated areas that have a low physician-population ratio. This is particularly true in the Panhandle and West Texas areas.

HISTORY OF PHYSICIANS PLACEMENT

The Relocation Service, as it was known in the beginning, grew out of the wartime Procurement and Assignment Service and has been carried on as a placement service for physicians by the staff of the central office of the Texas Medical Association under the direction of the office of the elected secretary. Between 1946 and 1948, the central office rendered a very informal type of service to physicians who wrote to or visited the central office. A simple card index file of communities needing a physician was maintained, and the names of places suitable for establishing a practice were supplied in reply to the inquiring physicians. Most of the inquiries were from returning medical officers. In 1949 this informal service was placed under the supervision of the state Council on Medical Economics. At that time a staff member of the central office was delegated the full responsibility of operating a "clearing house" type of informational service to the communities indicating need of a physician and to the physicians seeking locations. Originated primarily to help physicians, the program of this placement service has been broadened to provide extensive assistance for all communities seeking adequate medical care.

STRUCTURE OF THE PLACEMENT SERVICE

The Physicians Placement Service is conducted in the central office of the Texas Medical Association as a function of the state Council on Medical Economics. The director of the service is Mrs. Wacille Johnson, who has been a member of the staff of the central office for three years. There is at present no field representative working for the Physicians Placement Service with the delegated responsibility of investigating and evaluating requests from communities for aid in obtaining a physician. Since this function would be a valuable adjunct to the services now offered to the inquiring physician, employment of a field representative is under consideration.

METHOD OF OPERATION

Requests from Doctors.—Requests come from doctors desiring aid in relocating their practice, from returning medical officers wanting a location, and from hospital interns and residents desiring information and guidance. In addition, copies of letters from physicians sent originally to the Physicians Placement Service of the American Medical Association are forwarded to the Texas Medical Association. These requests are answered promptly by a mimeographed letter acknowledging receipt and describing the services rendered by the office. This answering letter is accompanied by a "location form," which is a questionnaire designed to collect information on the physician's educational background, his age, date and place of birth, experience in medical practice, military service and military status, and his preferences as to type of practice and size of community, as well as the date that he will be available for practice. When the completed questionnaire is returned by the physician, Mrs. Johnson places his name and address on the mailing list of available physicians desiring locations in Texas. Then he is sent a booklet, "Location Opportunities for Physicians in Texas," which describes current location opportunities in the state for both general practice and specialty practice. Each month he receives a supplementary booklet containing all new locations and names of the towns where openings have been filled so that he may bring his booklet up-to-date. From the information in the booklet, he may form his own evaluation of the desirability of the location, the ability of the community to support a practice, its interest in having a doctor, and the need of the community. To keep its listing of physicians current, the placement service sends letters every three months asking the physicians to advise if they have located or still desire to be on the mailing list.

Requests from Communities.—Letters from responsible citizens in a community, such as mayors, local pharmacists, and members of the chamber of commerce, come to the Physicians Placement Service requesting aid in obtaining a physician for their town. This office is also advised by the Selective Service System of the imminent call of a physician located in a small community, usually 30 to 60 days prior to the date of call. In this way efforts can be made to secure a replacement before the physician must leave the community. In addition to these methods of learning about locations needing a physician, the office receives referrals of requests from communities seeking to obtain a physician from the Physicians Placement Service of the American Medical Association and the deans of the medical schools in Texas. The placement service acknowledges these requests by a personal letter explaining the services that are available to the community. If the request is not from a physician seeking an associate, the correspondent is advised that the need for a physician must be verified by the secretary of the local county medical society and that this will require a short delay in follow-up. The placement office then contacts the secretary of the county society in whose county the request originated to confirm that the request is bona fide. He is asked to complete a questionnaire designed to collect information that can best be supplied by a professional man familiar with local circumstances. His opinion is asked regarding the validity of the request, the need of the community for more doctors, the desirability of the location to a physician and his family, and whether a new physician in that territory could obtain staff privileges at the nearest hospital.

After the need has been confirmed, the placement service sends a letter containing a list of physicians desiring locations in Texas and a questionnaire to the "contact man" in this community. In its letter the placement service suggests that it will furnish on request any further information about any of the listed physicians, such as age, training, military status, or other data that are maintained on file. The questionnaire is designed to gain information concerning the medical care

SALT-POOR DIET AND JEWISH DIETARY LAWS

To the Editor:—A salt-poor diet prescribed in cases of hypertension or congestive heart failure causes difficulties when prescribed to a person strictly adherent to Jewish dietary laws. These laws demand, for the purpose of removing any traces of blood from the surface of the meat, that it be abundantly salted before use. To eat meat without this preparation creates a religious problem and a conflict for the observing Jewish patient. Such meat has indeed a much higher sodium content than similar unprocessed material. Some Jewish hospitals tried to avoid the problem by using ammonium chloride instead of salt. According to Jewish law, this or the substitution of sugar for salt is not permissible.

For a long time, I have used the following method to solve the difficulty. The patient was told that, after salting the meat in the religiously prescribed way, he should put it in water for one and a half or two hours and change the water two to three times during this time. It is also my procedure to allow patients on a salt-poor diet to eat only boiled (not fried or broiled) meat and not the soup. It has never been proved that boiled meat loses any of its essential nutrients or has a lower food value than broiled or fried meat. In an effort to determine the sodium content of salted and unsalted meat prepared in various ways, investigations were performed in the Food Research Laboratories, Inc., in Long Island City. Samples of the different materials were ashed by digestion with perchloric acid and hydrogen peroxide, the meat samples having been prepared before by grinding in a food chopper. Sodium determinations were made by means of the Beckman flame photometer. To find out whether there are typical differences in the sodium content of different types of meat, one part of each sample remained unsalted, "the untreated piece." It was compared with a part from the same sample salted according to the usual Jewish dietary laws, "the treated piece." The difference in sodium content was:

	Moisture, %		Na, Mg./100 Gm.	
Cut	Untreated	Treated	Untreated	Treated
Brisket end	61.6	61.0	69.0	284
Single chuck	64.1	64.1	42.4	222
Breast flank	56.2	55.8	52.6	195
Average	60.8	60.3	54.7	234

After these preliminary investigations the intended experiments could be started. On four pieces of raw beef, each weighing approximately 500 gm., the salting process was carried out equally in each piece in the following way. After soaking for one-half hour in sufficient cold water to cover them, the pieces of beef were placed on a tilted platform and were sprinkled by hand with coarse salt. In order to equal the usual kitchen procedure, the amounts of salt were not measured, and, therefore, not exactly the same amount was used for each piece. After standing for one hour after the salt was added, the pieces were rinsed under running tap water and drained. A small slice was then cut from each piece, and the four slices thus obtained were composited for analysis without further treatment. These pieces were sample 0 shown in the second table. One piece of beef was then covered with cold water, brought to a boil, and simmered until tender (about one and one-half hours). The broth in which this piece was cooked was discarded and the meat saved for analysis as sample 1. A second piece of beef was covered with cold water and allowed to soak for one-half hour. The water was then poured off and replaced with fresh water in which the meat was cooked as described for sample 1. About 700 to 1,000 ml. of broth remained after cooking in this case and also in samples 3 and 4 described. Both the meat and the broth were saved for analysis and identified as sample 2. The third piece of beef was soaked for one-half hour in three consecutive changes of cold water in quantities sufficient to cover the meat. The meat was then immersed in fresh cold water and cooked as above. The meat and broth were identified as sample 3. The fourth piece of beef was soaked for one-half hour in three consecutive changes of hot tap water (165 F). The meat was then cooked as described above. The meat and broth were identified as sample 4. Equal samples of the cooked meat were prepared after grinding. Aliquots of meat and broth were ashed with perchloric acid and hydrogen peroxide, and sodium determinations were made on the residue. The results obtained are shown in the second table.

		Na Found	
Sample	Treatment	Meat, Mg./100 Gm.	Broth, Mg./100 Ml.
0	Salted, unsoaked	390	...
1	0, cooked	75	...
2	0, *single cold soak, cooked*	63	122
3	0, triple cold soak, cooked	76	89
4	0, triple warm soak, cooked	58	22

One other experiment was performed. Since, in the average kitchen, the amount of salt put on the pieces of meat is taken haphazardly, a greater amount of salt was used for the treating process. A single piece of raw beef weighing about 5 lb. (2.3 kg.) was divided into three equal portions. An adequate part of each portion was removed and composited to form a control sample. One portion was boiled without addition of salt, and meat as well as broth was analyzed for the sodium content. The two remaining portions were salted, and a small slice of each was taken for study before cooking. One piece was boiled in water, and meat and broth were analyzed. The third piece was cut in two and broiled. The next table shows the results of this procedure.

Sample Analyzed	Na Found, Mg./100 Gm.
Raw, unsalted	64.9
Unsalted, boiled	34.6
Broth from unsalted, boiled meat	23.6
Raw, salted (treated)	705.0
Treated, boiled	334.0
Broth from treated, boiled meat	372.0
Treated, broiled	375.0

The data obtained prove first that the processing of raw meat according to Jewish dietary law increases the sodium content remarkably. From the second table it can be seen that, if salting is not excessive, cooking takes out practically all of the added sodium. The sodium content of the differently prepared specimens in the same table is very close to that found in meat not salted before cooking. This proves that the moderate amount of salt added goes into the soup in the cooking. It is justifiable, in a salt-poor diet, not to permit the patient to eat the soup if the meat was processed before in the ritual way and not to allow him to eat fried or broiled meat of this kind. It is clear, on the other hand, from the figures in the second table that soaking the salted meat in cold or warm water before cooking removes the salt sprinkled on the surface quite well, especially if that soaking is in warm water and the amount of salt is not excessive.

In the second experiment, the sodium content of the meat was much higher than in the first. This was probably due to the high amount of salt used. It can also be seen that when the salted meat was not soaked twice for half an hour its salt content remained high and boiling removed only a little more than half the salt content. It is interesting to note that broiling reduced the sodium content to a high degree, but not so much as boiling does. Apparently, a considerable amount of the salt put on the surface of the piece is carried away by the dripping fluid during broiling. It seems that if treated meat is to be used in a salt-poor diet, the cook should use a minimum of salt, allow the meat to stand only for the religiously permissible minimum of time, cook the meat in a generous amount of fluid and throw the broth away.

COUNCIL ON MEDICAL SERVICE

This is the seventh in the series of articles on Physicians Placement written by medical students from Northwestern University Medical School after visiting the states for the purpose of studying the program on the state level.

PLACEMENT OF PHYSICIANS IN TEXAS

STATE CONDITIONS IN GENERAL

In most areas the state of Texas is adequately supplied with physicians. Within its boundaries there is one physician for every 813 persons. This physician population ratio compares favorably with the national average of one physician to every 730 persons. But, because Texas has so many square miles of sparsely populated land, the larger proportion of the physicians are located in towns ranging from 1,000 to 25,000. Even in view of this, the acknowledged need for more physicians is in towns with populations less than 25,000. Geographically, the maldistribution of physicians can be pointed up by considering roughly the eastern and western portions of the state. The eastern half is well populated and has more than an adequate number of physicians in relation to population. The western half, including the Panhandle, is, in general, sparsely populated range land with fewer physicians in relation to population. Of the 254 counties in Texas, a survey in 1951 showed that 10 had no physician. All of the 10 counties were in the western part of the state. Of these 10, only one area indicated a population concentration sufficient to support a physician.

The attitude of the people toward travel affects the demand for medical care. In the western areas, persons will travel as much as 30 or even 50 miles without complaint to reach a physician. In the eastern areas with the greater concentration of people, patients prefer to have medical service located, so to speak, at their fingertips. There are, in Texas, a large number of privately owned hospitals. The staff of such a hospital is frequently closed, because the present staff owns the hospital. This situation sometimes discourages additional physicians from entering such areas, but the Hill-Burton program now offers some relief. Another factor complicating medical practice in some areas is the number of "cultists." They tend to gravitate toward the sparsely populated areas that have a low physician-population ratio. This is particularly true in the Panhandle and West Texas areas.

HISTORY OF PHYSICIANS PLACEMENT

The Relocation Service, as it was known in the beginning, grew out of the wartime Procurement and Assignment Service and has been carried on as a placement service for physicians by the staff of the central office of the Texas Medical Association under the direction of the office of the elected secretary. Between 1946 and 1948, the central office rendered a very informal type of service to physicians who wrote to or visited the central office. A simple card index file of communities needing a physician was maintained, and the names of places suitable for establishing a practice were supplied in reply to the inquiring physicians. Most of the inquiries were from returning medical officers. In 1949 this informal service was placed under the supervision of the state Council on Medical Economics. At that time a staff member of the central office was delegated the full responsibility of operating a "clearing house" type of informational service to the communities indicating need of a physician and to the physicians seeking locations. Originated primarily to help physicians, the program of this placement service has been broadened to provide extensive assistance for all communities seeking adequate medical care.

STRUCTURE OF THE PLACEMENT SERVICE

The Physicians Placement Service is conducted in the central office of the Texas Medical Association as a function of the state Council on Medical Economics. The director of the service is Mrs. Wacille Johnson, who has been a member of the staff of the central office for three years. There is at present no field representative working for the Physicians Placement Service with the delegated responsibility of investigating and evaluating requests from communities for aid in obtaining a physician. Since this function would be a valuable adjunct to the services now offered to the inquiring physician, employment of a field representative is under consideration.

METHOD OF OPERATION

Requests from Doctors.—Requests come from doctors desiring aid in relocating their practice, from returning medical officers wanting a location, and from hospital interns and residents desiring information and guidance. In addition, copies of letters from physicians sent originally to the Physicians Placement Service of the American Medical Association are forwarded to the Texas Medical Association. These requests are answered promptly by a mimeographed letter acknowledging receipt and describing the services rendered by the office. This answering letter is accompanied by a "location form," which is a questionnaire designed to collect information on the physician's educational background, his age, date and place of birth, experience in medical practice, military service and military status, and his preferences as to type of practice and size of community, as well as the date that he will be available for practice. When the completed questionnaire is returned by the physician, Mrs. Johnson places his name and address on the mailing list of available physicians desiring locations in Texas. Then he is sent a booklet, "Location Opportunities for Physicians in Texas," which describes current location opportunities in the state for both general practice and specialty practice. Each month he receives a supplementary booklet containing all new locations and names of the towns where openings have been filled so that he may bring his booklet up-to-date. From the information in the booklet, he may form his own evaluation of the desirability of the location, the ability of the community to support a practice, its interest in having a doctor, and the need of the community. To keep its listing of physicians current, the placement service sends letters every three months asking the physicians to advise if they have located or still desire to be on the mailing list.

Requests from Communities.—Letters from responsible citizens in a community, such as mayors, local pharmacists, and members of the chamber of commerce, come to the Physicians Placement Service requesting aid in obtaining a physician for their town. This office is also advised by the Selective Service System of the imminent call of a physician located in a small community, usually 30 to 60 days prior to the date of call. In this way efforts can be made to secure a replacement before the physician must leave the community. In addition to these methods of learning about locations needing a physician, the office receives referrals of requests from communities seeking to obtain a physician from the Physicians Placement Service of the American Medical Association and the deans of the medical schools in Texas. The placement service acknowledges these requests by a personal letter explaining the services that are available to the community. If the request is not from a physician seeking an associate, the correspondent is advised that the need for a physician must be verified by the secretary of the local county medical society and that this will require a short delay in follow-up. The placement office then contacts the secretary of the county society in whose county the request originated to confirm that the request is bona fide. He is asked to complete a questionnaire designed to collect information that can best be supplied by a professional man familiar with local circumstances. His opinion is asked regarding the validity of the request, the need of the community for more doctors, the desirability of the location to a physician and his family, and whether a new physician in that territory could obtain staff privileges at the nearest hospital.

After the need has been confirmed, the placement service sends a letter containing a list of physicians desiring locations in Texas and a questionnaire to the "contact man" in this community. In its letter the placement service suggests that it will furnish on request any further information about any of the listed physicians, such as age, training, military status, or other data that are maintained on file. The questionnaire is designed to gain information concerning the medical care situation in the community as well as all of the advantages that the community can offer a doctor in the form of office or clinic facilities, opportunity for home life, and any special arrangements offered as inducement to a physician. Mrs. Johnson believes that community projects such as these are strong indications that the people are interested in having a physician and will support his practice. From the questionnaires executed by the county medical society and the community, information describing the location is compiled, mimeographed, and included in a booklet, "Location Opportunities for Physicians in Texas." Copies of this booklet are sent to all physicians seeking location in Texas.

Recently the style of this booklet was changed because the listing became too large, containing nearly 100 openings for general practitioners and specialists. Listings require cutting new stencils every three months in order to keep up-to-date and maintain alphabetization by county. A single change required a complete recutting of the entire listing and, therefore, much time and duplication of effort. To reduce the work involved in keeping the listing current, the information on each opening is cut on a separate stencil, and many copies are mimeographed at one time. Booklets are easily assembled and easily revised, since a single change now requires the recutting of but one stencil. Booklets listing openings in general practice and openings in various specialties are prepared separately. Physicians have received the booklet favorably because each location has been discussed in sufficient detail to be useful in helping to decide which locations should be investigated further. The items of information on each opening include the name of the community and county in which it is located, general section of the state, population of the community and surrounding trade area, number of physicians in practice or distance the residents must travel to each nearest physician, the distance to hospital facilities, the possibility of staff membership for a new practitioner in the area, and names of the nearest large towns. Also listed are any special inducements that the town is prepared to offer, such as housing, office space, and office equipment. Other items listed are major sources of income in the community, number of churches and their denominations, school facilities, facilities for recreation, and the name and address of the person to contact. Every three months when the booklet is revised, copies are sent to the administrators of hospitals in Texas having approved intern-resident training programs, to the deans of all Texas medical schools, and to other interested organizations outside of the state, so that they may be posted and made available to medical students, interns, and interested persons. A mimeographed letter accompanies these booklets inviting requests for additional copies and stating that the services of the placement service are available on request.

Policy Toward a Community That Does Not Qualify for Listing.—Infrequently, county society investigations of a community requesting aid reveal that the need is questionable. There may be many reasons; it may be a seasonal resort area with a large fluctuation in population that would make it impossible for a physician to earn a living during the off-season time of the year. The population concentration may be too small to support a physician, or the area may have such a low income per capita that it may not be able to support a physician. Sometimes the request is from an area adequately provided with medical care in adjacent areas, so that there is no real need for another physician there. These and various other reasons may make the location unsuitable for listing as an opening for a medical practice. In each case, Mrs. Johnson writes a letter to the community stating that the Physicians Placement Service office is sympathetic with the situation there, but, because the need for a physician was not confirmed by the local county medical society (the stated reasons are included), her office cannot list the community in the regular publications.

Statistics.—A final review of the number of physicians and communities aided by the placement service provides some idea as to the extent and effectiveness of the service rendered the people and physicians in the state by this activity of the Texas Medical Association. Between January, 1952, and January, 1953, the Physicians Placement Service handled requests from 399 physicians seeking locations in Texas. One hundred of this number located in Texas, and 136 we dropped from the list for various reasons. Some physicia had resumed medical training, some had entered milit service, and others had located in other states. There we at the end of the year, 163 physicians who were still interest in locations in Texas on the mailing list. During the sa one year period, the placement service had requests for from 180 communities in the state seeking a physician. Six five of these locations were filled, and 26 were removed fr the list for various reasons. As of August, 1953, the Physici Placement Service had a mailing list composed of 96 co munities seeking physicians and of 122 physicians seeki locations in Texas.

DOCTOR DISTRIBUTION PROGRAM

Although satisfied that the placement service is renderi a service to the fullest extent of its ability and responsibili the Texas Medical Association believed that a more dir effort to overcome the maldistribution of physicians in Te should be investigated and undertaken. Accordingly, the pub relations committee in conjunction with the rural health co mittee proposed to the board of trustees of the associati that a "special committee on doctor distribution" be form to conduct a series of surveys covering the major aspects the distribution and availability of medical care and person in the state. Subsequently, this proposal was brought bef the house of délegates, which voted funds for the operati of this special committee.

Four Point Program.—The program of the Special Comm tee on Doctor Distribution was divided into four phases. T first two phases consisted of conducting surveys to determi facts about the Texas physicians and to learn what the la want. The last two phases consisted of direct contact w communities in order to investigate any need indicated the surveys and to aid communities to develop programs secure physicians. The entire program is designed to supp ment the efforts of the Physicians Placement Service. It w in no manner compete with the present placement service supplant the need for an active placement service. It is hop by the Texas Medical Association that this program will bri about public understanding of its efforts to secure a bet distribution of doctors throughout the state. Such a progra may also help to offset criticism that has arisen in some are where there seemed to be a lack of medical service and whe however, it became evident upon investigation by the coun society that a physician either was not needed or could n be supported. In these cases, the only course remaining f the placement service was to try to inform the communi tactfully of the facts. In a few instances this has stimulat a feeling that the Texas Medical Association is not willing help the community involved. The association believes that definite plan should be worked out to show the people why would be very hard to interest a doctor to settle in such location. This will be part of the responsibility of the Speci Committee on Doctor Distribution.

The first phase of the program has been completed. Th was a survey to ascertain the mass viewpoint of the medic profession as to the distribution of doctors in Texas. Ov 6,500 questionnaires were mailed to Texas physicians. The was an overwhelming response by the profession; over 6,0 questionnaires were completed and returned. Included in t questionnaire were questions as to the type of practice e gaged in, age of physician, years of practice, percentage time spent in practice, type of calls made, average numbe of patients per doctor, and other questions, such as the ph sician's opinion of his county's ability to provide adequat medical care. The second phase of the program is to dete mine what the people want. Plans are being developed t conduct a survey by dividing the state according to council or districts, which is the system of division in the state medi cal society. In each district, a three-man committee consistin of a counselor and two assistants has been set up and author ized to make an on-the-spot survey of the situation. From the answers to their questions, the committee will grade th needs of the communities. The grading and evaluation of th degree of urgency of need and the desirability of the locatio to a physician is the third phase of the special committee's program, and it will be accomplished by applying the new priority rating plan developed by the American Medical Association. This will be the first attempt on a state-wide basis to apply the priority rating and may well determine its usefulness in other parts of the U. S. With the information gained by this survey and with an accurate picture of the relative degree of need and desirability of the communities requesting a physician, the medical association will be in a better position to show the doctors desiring a location the relative merit of each location. The association will be able to increase its efforts to help the communities most in need and to point up to a community with a low desirability priority rating the steps it can take to increase its attractiveness to a physician.

The fourth phase of the program is to show the community that needs a physician how it may best attract him, or to explain to the community why it does not need a physician. To aid in this the committee on doctor distribution is preparing a booklet, "My Town Needs a Doctor," setting forth definite plans on how to make a community more attractive to a physician and also giving pertinent reasons why some communities will not be able to secure a doctor's services. It is hoped that such a procedure will lessen the degree of misunderstanding that has arisen in some communities as a result of their inability to get a doctor to locate there and serve them. The over-all accomplishment of such a program should be a major contribution in ascertaining accurately the needs of rural communities for more physicians and should convince the people of Texas that the Texas Medical Association is definitely attempting to solve the problem of maldistribution of physicians in the state.

Trial Run of Program.—Because Texas is such a large state and many unforeseen problems may be involved in carrying out the entire program of the special committee, plans are under way for a trial run in a central district that includes 10 counties. Letters outlining the program will be sent to the presidents of the county medical societies in the district. Simultaneously, letters will go to the physicians practicing in the district, inviting their opinions on the need for additional physicians in their communities. Later letters will be sent to the secretaries of the chambers of commerce in the district, explaining the survey and inviting them to contact the committee if they believe additional physicians are needed in their communities. The replies from communities indicating a desire for additional physicians will be acknowledge, and the booklet, "My Town Needs a Doctor," will be sent to them. It is an eight-page folder with outlined suggestions stressing community responsibility in getting and holding doctors. Subsequently, the counselor of the district and his committee will go to the town and talk to any doctors located there and to members of the chamber of commerce or the mayor. In the presence of all interested, the committee will apply the A. M. A. priority rating system to the community to evaluate the degree of need and desirability. If the town cannot support a practice of medicine or does not need a doctor, there will be evidence to explain the situation. If the town is in need of a doctor, its citizens will be assured that the placement service will help them.

Increased Service with State-Wide Plan.—After the Special Committee on Doctor Distribution has made a trial run and ascertained the success of the program, a full-range plan will be set up for the entire state, which will integrate the efforts of the special committee and the placement service. The communities in the state that are found in need of additional physicians will be referred to the placement service office. The regular procedure of sending listings of physicians seeking locations to the towns and of gaining information from the towns will be followed as in the past. The communities will be listed in the booklet "Location Opportunities in Texas for Physicians," which will be sent to all physicians on the mailing list. The placement service will supplement the efforts of the special committee in helping the community to develop an active program to attract a physician. To do this, the office will send to the community the new A. M. A. booklet, "A Doctor for Your Community," designed to assist the communities with ideas on developing, expanding, or improving their present facilities for a physician. Eventually the placement service hopes to have a representative from their office personally visit all communities requesting assistance and help them solve their problems. Having a field representative would obviate the need of all of the questionnaires and form letters now used, since he could collect information on the spot.

PROGRAMS ENCOURAGING GENERAL PRACTICE

Loan Fund.—A controversial course was launched in 1952 when an amendment to the state constitution was put before the citizens by referendum. The amendment established a state program and fund to subsidize the cost of educating medical personnel. It read:

> The legislature shall create a State Medical Education Board to be composed of not more than six members whose qualifications, duties and terms of office shall be prescribed by law. The Legislature shall also establish a State Medical Education Fund and make adequate appropriations therefore to be used by the State Medical Education Board to provide grants, loans or scholarships to students desiring medicine and agreeing to practice in the rural areas of this State, upon such terms and conditions as shall be prescribed by law. The term "rural areas" as used in this Section shall be defined by law.

The opponents of this amendment pointed out several weak features, which were summarized in the *San Antonio Express* and other Texas newspapers:

> The term "medical" is not defined. It is left to the legislature to determine whether it would include dentists, veterinarians, osteopaths, chiropractors, nurses and technicians.
>
> There is no limit on the number of persons whose education could be subsidized or on the amount of money the legislature must appropriate to operate the board and fund.
>
> It is a step toward socialized medicine.
>
> Additional funds to be appropriated would not be available within present estimates of state income and would require further taxes.
>
> It does not restrict assistance to Texas citizens nor require that medical education financed under it would be acquired in Texas schools.
>
> Another board or bureau would be added to the already unwieldy state governmental structure.[1]

Although the organized medical profession in Texas took "a dim view of the amendment,"[2] it passed by a small margin. Since that time, the legislature has not enacted a program nor provided funds for its operation.

Preceptorships.—The University of Texas Medical Branch, in cooperation with the Texas Medical Association and the Texas Academy of General Practice, has an active preceptorship program. Each senior medical student must apprentice himself for 11 weeks to an approved "preceptor" before he may graduate. He lives and works with his "father in medicine" in private practice. The Texas medical profession and the university expect to see a sharp increase in the number of young physicians seeking to practice medicine in rural areas.

Postgraduate and Refresher Courses.—Physician members of county medical societies frequently are privileged to hear top-notch scientific programs in their home communities by means of postgraduate telephone broadcasts staged under the active sponsorship of the Texas Medical Association. From one of the teaching centers of the state, a program originates consisting of a discussion by experienced clinicians and teachers on a selected topic. Certain visual aids are made available to the listeners with each program from the special committee on postgraduate work. With this arrangement, there is little difference from the listener's viewpoint in hearing the program or actually being in the presence of the speakers. The University of Texas School of Medicine has organized teams that are available to county medical societies anywhere in the state for short-term refresher courses in pediatrics, obstetrics and gynecology, medicine, surgery, physical medicine, basic sciences, and tumor clinics.

The Postgraduate School of Medicine of the University of Texas, with its central division in Houston and subdivisions in San Antonio, San Angelo, Temple, Lubbock, Corpus Christi, and Tyler, offers postgraduate refresher courses. This dispersion of the faculty brings the courses closer to the physicians in outlying areas. Baylor University College of Medicine and Southwestern Medical School of the University of Texas also have postgraduate refresher courses throughout the year. The Academy of General Practice sponsors refresher courses primarily for general practitioners during the year. The Texas division of the American Cancer Society, usually in collaboration with the local county medical societies, sponsors weekly

2. Houston Chronicle, Sept. 29, 1952.

tumor clinics in many places in the state. Both the Postgraduate Medical Assembly of South Texas and the International Postgraduate Medical Assembly of Southwest Texas hold regular meetings for physicians. There are various clinical conferences held throughout the state. The Dallas Southern Clinical Society holds spring conferences and short refresher courses throughout the year. In Wichita Falls, Waco, and Fort Worth, one day clinical conferences are held for interested physicians.

Special Services Available to Rural Physicians.—The M. D. Anderson Hospital for Cancer research, diagnosis, and treatment is open to patients referred from physicians throughout Texas. The University of Texas Medical Branch in Galveston, with its hospitals, laboratory facilities, and faculty, is available for consultation and care of referred patients.

Expansion Program for Medical Schools.—The legislature has appropriated funds for the expansion of the present state-subsidized medical schools. The first unit of permanent buildings will be built in Dallas at Southwestern Medical School, which has been in operation in temporary quarters for several years. The expansion program of the University of Texas Medical Branch in Galveston is in the final stages of completion. The funds for the program were appropriated by the legislature from the general funds. The expanded facilities will increase the teaching capacity of the school approximately 25%.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Malpractice: Childbirth.—This was a suit for damages against the defendant physician for alleged negligent treatment and care during an obstetric case. From a judgment in favor of the plaintiff, the defendant physician appealed to the Supreme Judicial Court of Massachusetts.

The defendant was an obstetrician of wide experience, whom the plaintiff first consulted on Aug. 29, 1946, when she was about four months pregnant with her first baby. It was agreed that he would give her prenatal care and would deliver her baby at a certain hospital in Cambridge, the city in which she lived. She visited his office every few weeks, and all was proceeding in a normal manner. Her sixth and last visit was on Jan. 6, 1947, within three or four weeks of her expected date of confinement. The defendant testified that on that occasion everything was normal, including the position of the fetus, which he did nothing to change as the head was engaged in the pelvis. On the other hand, the testimony of the plaintiff was that on that occasion the defendant caused her to lie on the examining table, listened to the fetal heart, and "turned the child"; that he placed his hands on each side of her abdomen, and with "a quick sharp motion he pushed his hands down so that what was in her stomach turned around"; that she felt a sharp pain and screamed, "What are you doing?"; that the defendant replied, "I pushed the child's head downward"; that she experienced "a terrible sharp gripping pain . . . all over her stomach"; and that he told her to expect the baby at any time, to call him at the first sign, and that he would come as soon as she called.

The plaintiff further testified that about 11 o'clock that same evening, while in bed, she felt a sudden gush of blood, which "hit down to her ankles" with great force. It was "coming down all the time," and she suffered great pain. The plaintiff's husband testified that about 11:30 p. m. he telephoned the defendant and told him that she was ready to go to the hospital, was gushing blood and suffering severe abdominal pain, and that the defendant should come immediately; that the defendant told him to observe the plaintiff for an hour and to call him back; that he observed the plaintiff's condition; that there was "more blood all over the blanket, a lot of blood"; that he called the defendant again in half an hour, he could not wait the full hour; that he told the defendant that she was continuing to bleed and was suffering great pain and asked what he should do; that the defendant said that it sounded like a separation of the placenta, and that the defendant would meet him at the hospital immediately; and that he then drove the plaintiff to the hospital, arriving at 12:30 a. m. What happened during the remainder of the night, said the court, is disputed. The defendant testified that he received a telephone call from the hospital at 1 a. m. and went there immediately, arriving at 1:30; that he examined the plaintiff and observed that she was in mild labor; that he was not certain that true labor had started; that her membranes had ruptured; that he observed no blood; that he concluded that the fetal heartbeats were normal; that after 15 minutes he went to another patient at another hospital; that, when he left, the baby was alive and "things were proceeding along"; that around 5 a. m. he received a telephone call from the night supervisor to the effect that the patient had become nauseated, vomited, and passed two blood clots, after which the nurse listened for the fetal heart beat, which had not been present for a half hour; that his diagnosis at that time was separation of the placenta, and he felt able to make that diagnosis from the telephone conversation; that after receiving "a call of that nature, passage of the blood, abdominal pain," his first duty was to go to the hospital immediately; that he always did that; that that was the accepted practice in the community; that he saw the plaintiff a little after 5 a. m.; and that he could not hear the fetal heartbeat, the obvious explanation being that the baby was probably dead and had died during his absence.

On the other hand, there was testimony from another patient that she was in the "labor room" with the plaintiff from about the time of her arrival; that she did not see the defendant there at any time between 1 a. m. and 3 a. m.; that she saw two doctors between 7:30 a. m. and 8:30 a. m.; and that they were the first men she saw in the room. The plaintiff testified that she saw no doctor before 3 a. m.; and that the first time she saw the defendant was in the morning daylight. The plaintiff's husband testified that he stayed at the hospital until 3:45 a. m.; that he did not see the defendant; that he received a telephone call from the defendant between 7 a. m. and 7:30 a. m.; that the defendant said, "I just arrived. Come down immediately. It is important, but don't be alarmed"; that he went to the hospital; and that then the defendant informed him that the plaintiff must have an operation. A cesarean operation was performed at 11 a. m. The baby was born dead. The defendant's diagnosis was confirmed. The placenta was completely detached. The plaintiff "had the ultimate in complication of abruptio placentae."

There was considerable expert testimony from the defendant. There are four types of separated placentas. In the type that the plaintiff developed, there is bleeding into the muscle fiber of the uterus. This is a very serious complication, and, when diagnosed properly, a cesarean operation should be performed and the uterus emptied as quickly as possible. It is unusual for the placenta to separate before the baby leaves the womb. There are a number of causes for such an occurrence: trauma; version, properly or improperly done; and any disturbance of any magnitude to the fetus or to the mother. A version is a procedure whereby the baby's position is changed externally. It means that if the buttocks were downward, the baby is turned around so that the head would be downward. The defendant testified that there was no version operation on the plaintiff because the head was always down; that he never told her that he performed a version operation; that version was one procedure he had been set against his whole life; that he had always taught and preached against it; that it was accepted practice in some places, some people did it, but that he did not do it, because he thought the procedure was highly dangerous.

On the evidence, said the court, it could have been found that the defendant made a diagnosis of a separated placenta as early as 12 p. m. on Jan. 6; that he did not see the plaintiff until dawn or 7 a. m. on Jan. 7; and that, in the type of separated placenta that the plaintiff had, when diagnosed properly, a cesarean operation should have been performed and the uterus emptied as quickly as possible. The jury could have found that the information that the husband testified he gave the defendant before midnight of the day before was similar to that that the defendant testified he received from the night supervisor, and that, in accordance with his own testimony as to the practice in the community, he should have gone to the hospital the night before or, in any event, before dawn. Moreover, if the jury believed that a version was performed on the plaintiff, they could find that the defendant had within 24 hours performed an act that he believed to be dangerous and that, however well done, could be a cause of a separated placenta. In these circumstances, the court concluded, without reference to the extracts from the medical treatises introduced in evidence, the jury could find that defendant did not exercise the care and skill required of him as an obstetrician. The plaintiff sustained harm. We cannot accept the defendant's argument that evidence of causal negligence was lacking. In view of the fact that there was substantial evidence to sustain the finding of the jury, the judgment of the trial court was affirmed and the defendant's exceptions overruled. *Thomas v. Ellis, 106 N. E. (2d) 687 (Massachusetts 1952).*

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—ED.

DISCUSSION OF THE FEE

Medical men must guard against living beyond their incomes or flashing funds in their communities. When a physician frankly discusses fees in advance with his patients, even to the point of describing just how he arrives at a fee, misconceptions about overcharging are eliminated. One doctor writes that, with 95% of his patients, three minutes at the end of the visit explaining the medical bill will insure financial success. If patients are made to feel that the physician is sincerely interested in the problems—financial as well as medical—the doctor-patient financial relationship can soon be much improved.

Both physician and patient may be reluctant or embarrassed to bring up the question of fees—if the patient does not inquire, it is the responsibility of the physician to open the subject as tactfully as possible. Because the doctor's responsibility to explain fees extends to other areas of medical care including hospital and drug costs, some societies in cooperation with local hospitals have worked up estimate sheets, which are filled out by the physician before a patient enters the hospital. Individual doctors occasionally work up their own estimate forms when a patient is embarking on long-term treatment.

From a successful physician comes this suggestion: "In estimating fees, if I am in doubt, I estimate the charge a little higher than it may be. Then the patient is pleased when he later receives a bill for a smaller sum." Most patients do not object to fair, understandable charges; they do object to unexplained, unexpected charges. It is up to America's physicians to prevent misconceptions about medical fees and medical economics.

Costs of illness can be reduced in many ways. Whenever possible, point out to patients that it is more economical to treat them in the office than in their home or at the hospital. The number of unnecessary calls can be reduced by more effectively using the telephone. For example, a patient who comes into your office for treatment of a minor condition can be told: "I doubt if you will have any more trouble but call me in a day or two and let me know how you are." This shows interest and yet saves the patient the price of an office call he may not need. The doctor can reduce medical costs, too, by performing only those tests and procedures that will directly help in diagnosis and treatment. One medical leader says: "Use hospitals and tests only as necessary; these are expensive items. Don't forget that overuse affects the insured just as much as the man who pays his bills directly; the premium simply goes up. Don't prescribe high cost items when a comparable low cost item is available. When cost is a factor in a case, don't write prescriptions for the costly newer drugs unless their use is clearly indicated, and their administration should not be continued unless positively favorable results are obtained in a reasonable period of time and minimal dosage determined."

Do not prescribe drugs in large quantities. This is a waste of the patient's money. Some patients are told by their physicians to buy 20 tablets when 10 would suffice. A physician may not have a real idea of the cost of the items he is prescribing. He can do his patients a real service by checking with local druggists and working up an informal comparative price list on various items. On this basis he can bring his patients' drug bills down somewhat.

Irritating to both physicians and patients alike is the house call that involves several members of the same family. For instance, a doctor is called to see little Johnny who has the flu. When he arrives, the mother and father also ask him to check the three other children. If he renders a bill for service to four children, the family is angry. Yet in a way it is an imposition to expect a physician to see four patients and receive payment for service to only one. The answer to this problem seems to lie in the amount of time the call necessitates. If extensive medical service is given to all four children, then certainly a higher bill is indicated. Otherwise, the physician may charge for one house call—or charge a slightly higher fee.

To sum up, the physician can save money for the patient by recommending office calls rather than house or hospital calls, if such procedure is clearly warranted; reducing unnecessary office visits by using telephone follow-ups; performing expensive tests only when necessary; using hospitals only when necessary; prescribing low-cost drugs rather than high-cost items when possible; and by prescribing only for quantities needed.

MEDICAL MOTION PICTURES

Retire to Life: 16 mm., black and white, sound, showing time 20 minutes. Produced by the University of Oklahoma for the Oklahoma State Department of Health, A. A. Hellams, Psychiatric Consultant. Procurable on rental or purchase from International Film Bureau, 57 East Jackson Blvd., Chicago 4.

This film contrasts retiring from life with retiring to life. The first two-thirds of the film shows the problems encountered subsequent to retirement by a man who had not planned in advance for his retirement and intended to spend the rest of his time fishing and loafing. He became increasingly morbid and terrifying until he reached the point where it would be difficult for the average person of his age to identify himself with the character in the film. After a young man acquainted him with the real problem and gave him useful employment that rehabilitated him, he managed to go through an adjustment very quickly.

The tempo of the entire film is slow. Owing to the frustrations of the main character in attempting to find his place in the world, it becomes a very heavy and oppressive story. It appears that the purpose of this film is to teach persons in their 50's and 60's the necessity of preparing for retirement and developing a willingness to retire to life rather than from something. It would be useful also for those who are concerned with counseling older persons in matters of health and social adjustment. This movie might be used with audiences of community workers and employers to make them more aware of the problems facing older persons. It would not, however, help old persons themselves to find more satisfying adjustments. In fact, it would be far more likely to arouse their anxiety. The photographic and sound qualities of this film are very good.

tumor clinics in many places in the state. Both the Postgraduate Medical Assembly of South Texas and the International Postgraduate Medical Assembly of Southwest Texas hold regular meetings for physicians. There are various clinical conferences held throughout the state. The Dallas Southern Clinical Society holds spring conferences and short refresher courses throughout the year. In Wichita Falls, Waco, and Fort Worth, one day clinical conferences are held for interested physicians.

Special Services Available to Rural Physicians.—The M. D. Anderson Hospital for Cancer research, diagnosis, and treatment is open to patients referred from physicians throughout Texas. The University of Texas Medical Branch in Galveston, with its hospitals, laboratory facilities, and faculty, is available for consultation and care of referred patients.

Expansion Program for Medical Schools.—The legislature has appropriated funds for the expansion of the present state-subsidized medical schools. The first unit of permanent buildings will be built in Dallas at Southwestern Medical School, which has been in operation in temporary quarters for several years. The expansion program of the University of Texas Medical Branch in Galveston is in the final stages of completion. The funds for the program were appropriated by the legislature from the general funds. The expanded facilities will increase the teaching capacity of the school approximately 25%.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Malpractice: Childbirth.—This was a suit for damages against the defendant physician for alleged negligent treatment and care during an obstetric case. From a judgment in favor of the plaintiff, the defendant physician appealed to the Supreme Judicial Court of Massachusetts.

The defendant was an obstetrician of wide experience, whom the plaintiff first consulted on Aug. 29, 1946, when she was about four months pregnant with her first baby. It was agreed that he would give her prenatal care and would deliver her baby at a certain hospital in Cambridge, the city in which she lived. She visited his office every few weeks, and all was proceeding in a normal manner. Her sixth and last visit was on Jan. 6, 1947, within three or four weeks of her expected date of confinement. The defendant testified that on that occasion everything was normal, including the position of the fetus, which he did nothing to change as the head was engaged in the pelvis. On the other hand, the testimony of the plaintiff was that on that occasion the defendant caused her to lie on the examining table, listened to the fetal heart, and "turned the child"; that he placed his hands on each side of her abdomen, and with "a quick sharp motion he pushed his hands down so that what was in her stomach turned around"; that she felt a sharp pain and screamed, "What are you doing?"; that the defendant replied, "I pushed the child's head downward"; that she experienced "a terrible sharp gripping pain . . . all over her stomach"; and that he told her to expect the baby at any time, to call him at the first sign, and that he would come as soon as she called.

The plaintiff further testified that about 11 o'clock that same evening, while in bed, she felt a sudden gush of blood, which "hit down to her ankles" with great force. It was "coming down all the time," and she suffered great pain. The plaintiff's husband testified that about 11:30 p. m. he telephoned the defendant and told him that she was ready to go to the hospital, was gushing blood and suffering severe abdominal pain, and that the defendant should come immediately; that the defendant told him to observe the plaintiff for hour and to call him back; that he observed the plaintiff's dition; that there was "more blood all over the blanket, of blood"; that he called the defendant again in half an hour, he could not wait the full hour; that he told t defendant that she was continuing to bleed and was sufferi great pain and asked what he should do; that the defenda said that it sounded like a separation of the placenta, and th the defendant would meet him at the hospital immediate and that he then drove the plaintiff to the hospital, arrivi at 12:30 a. m. What happened during the remainder of t night, said the court, is disputed. The defendant testified t he received a telephone call from the hospital at 1 a. m. a went there immediately, arriving at 1:30; that he examin the plaintiff and observed that she was in mild labor; that was not certain that true labor had started; that her me branes had ruptured; that he observed no blood; that concluded that the fetal heartbeats were normal; that af 15 minutes he went to another patient at another hospit that, when he left, the baby was alive and "things w proceeding along"; that around 5 a. m. he received a telepho call from the night supervisor to the effect that the pati had become nauseated, vomited, and passed two blood cl after which the nurse listened for the fetal heart beat, whi had not been present for a half hour; that his diagnosis that time was separation of the placenta, and he felt able make that diagnosis from the telephone conversation; t after receiving "a call of that nature, passage of the blo abdominal pain," his first duty was to go to the hospi immediately; that he always did that; that that was the cepted practice in the community; that he saw the plain a little after 5 a. m.; and that he could not hear the fe heartbeat, the obvious explanation being that the baby w probably dead and had died during his absence.

On the other hand, there was testimony from anot patient that she was in the "labor room" with the plaintiff fr about the time of her arrival; that she did not see the fendant there at any time between 1 a. m. and 3 a. m.; t she saw two doctors between 7:30 a. m. and 8:30 a. m.; a that they were the first men she saw in the room. T plaintiff testified that she saw no doctor before 3 a. m.; a that the first time she saw the defendant was in the morn daylight. The plaintiff's husband testified that he stayed the hospital until 3:45 a. m.; that he did not see the defenda that he received a telephone call from the defendant betw 7 a. m. and 7:30 a. m.; that the defendant said, "I j arrived. Come down immediately. It is important, but do be alarmed"; that he went to the hospital; and that then t defendant informed him that the plaintiff must have operation. A cesarean operation was performed at 11 a. The baby was born dead. The defendant's diagnosis was co firmed. The placenta was completely detached. The plaint "had the ultimate in complication of abruptio placentae."

There was considerable expert testimony from the defenda There are four types of separated placentas. In the type th the plaintiff developed, there is bleeding into the muscle fib of the uterus. This is a very serious complication, and, wh diagnosed properly, a cesarean operation should be perform and the uterus emptied as quickly as possible. It is unusu for the placenta to separate before the baby leaves the wom There are a number of causes for such an occurren trauma; version, properly or improperly done; and any d turbance of any magnitude to the fetus or to the mother. version is a procedure whereby the baby's position is chang externally. It means that if the buttocks were downwar the baby is turned around so that the head would be dow ward. The defendant testified that there was no versi operation on the plaintiff because the head was always dow that he never told her that he performed a version operatio that version was one procedure he had been set against h whole life; that he had always taught and preached again it; that it was accepted practice in some places, some peopl did it, but that he did not do it, because he thought th procedure was highly dangerous.

On the evidence, said the court, it could have been foun that the defendant made a diagnosis of a separated placent as early as 12 p. m. on Jan. 6; that he did not see the plaintiff until dawn or 7 a. m. on Jan. 7; and that, in the typ of separated placenta that the plaintiff had, when diagnose properly, a cesarean operation should have been performe and the uterus emptied as quickly as possible. The jury coul have found that the information that the husband testified he gave the defendant before midnight of the day before was similar to that that the defendant testified he received from the night supervisor, and that, in accordance with his own testimony as to the practice in the community, he should have gone to the hospital the night before or, in any event, before dawn. Moreover, if the jury believed that a version was performed on the plaintiff, they could find that the defendant had within 24 hours performed an act that he believed to be dangerous and that, however well done, could be a cause of a separated placenta. In these circumstances, the court concluded, without reference to the extracts from the medical treatises introduced in evidence, the jury could find that defendant did not exercise the care and skill required of him as an obstetrician. The plaintiff sustained harm. We cannot accept the defendant's argument that evidence of causal negligence was lacking. In view of the fact that there was substantial evidence to sustain the finding of the jury, the judgment of the trial court was affirmed and the defendant's exceptions overruled. *Thomas v. Ellis, 106 N. E. (2d) 687 (Massachusetts 1952).*

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—Ed.

DISCUSSION OF THE FEE

Medical men must guard against living beyond their incomes or flashing funds in their communities. When a physician frankly discusses fees in advance with his patients, even to the point of describing just how he arrives at a fee, misconceptions about overcharging are eliminated. One doctor writes that, with 95% of his patients, three minutes at the end of the visit explaining the medical bill will insure financial success. If patients are made to feel that the physician is sincerely interested in the problems—financial as well as medical—the doctor-patient financial relationship can soon be much improved.

Both physician and patient may be reluctant or embarrassed to bring up the question of fees—if the patient does not inquire, it is the responsibility of the physician to open the subject as tactfully as possible. Because the doctor's responsibility to explain fees extends to other areas of medical care including hospital and drug costs, some societies in cooperation with local hospitals have worked up estimate sheets, which are filled out by the physician before a patient enters the hospital. Individual doctors occasionally work up their own estimate forms when a patient is embarking on long-term treatment.

From a successful physician comes this suggestion: "In estimating fees, if I am in doubt, I estimate the charge a little higher than it may be. Then the patient is pleased when he later receives a bill for a smaller sum." Most patients do not object to fair, understandable charges; they do object to unexplained, unexpected charges. It is up to America's physicians to prevent misconceptions about medical fees and medical economics.

Costs of illness can be reduced in many ways. Whenever possible, point out to patients that it is more economical to treat them in the office than in their home or at the hospital. The number of unnecessary calls can be reduced by more effectively using the telephone. For example, a patient who comes into your office for treatment of a minor condition can be told: "I doubt if you will have any more trouble but call me in a day or two and let me know how you are." This shows interest and yet saves the patient the price of an office call he may not need. The doctor can reduce medical costs, too, by performing only those tests and procedures that will directly help in diagnosis and treatment. One medical leader says: "Use hospitals and tests only as necessary; these are expensive items. Don't forget that overuse affects the insured just as much as the man who pays his bills directly: the premium simply goes up. Don't prescribe high cost items when a comparable low cost item is available. When cost is a factor in a case, don't write prescriptions for the costly newer drugs unless their use is clearly indicated, and their administration should not be continued unless positively favorable results are obtained in a reasonable period of time and minimal dosage determined."

Do not prescribe drugs in large quantities. This is a waste of the patient's money. Some patients are told by their physicians to buy 20 tablets when 10 would suffice. A physician may not have a real idea of the cost of the items he is prescribing. He can do his patients a real service by checking with local druggists and working up an informal comparative price list on various items. On this basis he can bring his patients' drug bills down somewhat.

Irritating to both physicians and patients alike is the house call that involves several members of the same family. For instance, a doctor is called to see little Johnny who has the flu. When he arrives, the mother and father also ask him to check the three other children. If he renders a bill for service to four children, the family is angry. Yet in a way it is an imposition to expect a physician to see four patients and receive payment for service to only one. The answer to this problem seems to lie in the amount of time the call necessitates. If extensive medical service is given to all four children, then certainly a higher bill is indicated. Otherwise, the physician may charge for one house call—or charge a slightly higher fee.

To sum up, the physician can save money for the patient by recommending office calls rather than house or hospital calls, if such procedure is clearly warranted; reducing unnecessary office visits by using telephone follow-ups; performing expensive tests only when necessary; using hospitals only when necessary; prescribing low-cost drugs rather than high-cost items when possible; and by prescribing only for quantities needed.

MEDICAL MOTION PICTURES

Retire to Life: 16 mm., black and white, sound, showing time 20 minutes. Produced by the University of Oklahoma for the Oklahoma State Department of Health, A. A. Hellams, Psychiatric Consultant. Procurable on rental or purchase from International Film Bureau, 57 East Jackson Blvd., Chicago 4.

This film contrasts retiring from life with retiring to life. The first two-thirds of the film shows the problems encountered subsequent to retirement by a man who had not planned in advance for his retirement and intended to spend the rest of his time fishing and loafing. He became increasingly morbid and terrifying until he reached the point where it would be difficult for the average person of his age to identify himself with the character in the film. After a young man acquainted him with the real problem and gave him useful employment that rehabilitated him, he managed to go through an adjustment very quickly.

The tempo of the entire film is slow. Owing to the frustrations of the main character in attempting to find his place in the world, it becomes a very heavy and oppressive story. It appears that the purpose of this film is to teach persons in their 50's and 60's the necessity of preparing for retirement and developing a willingness to retire to life rather than from something. It would be useful also for those who are concerned with counseling older persons in matters of health and social adjustment. This movie might be used with audiences of community workers and employers to make them more aware of the problems facing older persons. It would not, however, help old persons themselves to find more satisfying adjustments. In fact, it would be far more likely to arouse their anxiety. The photographic and sound quality of this film are very good.

Spontaneous Hypoglycemia Owing to Occult Insulinoma.—A diagnosis of insulinoma is indicated whenever a patient presents the criteria constituting Whipple's triad. These are (1) signs and symptoms of insulin shock, usually progressive and often induced by fasting or exercise; (2) repeated fasting blood sugar concentrations below 50 mg. per 100 cc.; and (3) symptomatic relief by dextrose administration. Insulinomas, or insulin-secreting islet cell adenomas of the pancreas, are frequently occult and may escape detection on surgical exploration. The adequacy of surgical therapy should, therefore, be substantiated at the operating table while the abdomen is open by (1) the demonstration of the tumor in the surgical specimen, confirmed by rapid histological examination, and (2) observation of a rise in the blood sugar level after resection, as compared with the base level obtained from blood drawn during the exploration of the abdomen before resection of the tumor. A comparative hyperglycemic response in t presence of an islet cell tumor demonstrated in the surgi specimen suggests that resection has been adequate. Failu to observe a significant rise in blood sugar indicates th further, and possibly even total, resection is needed. Subto pancreatectomy (at least to the right of the superior mesente vessels) may be expected to prove adequate in 75% of ca of occult adenomas; it should provide a 50% chance of cu for hypoglycemia owing to pancreatic hyperplasia and shou also benefit two-thirds of the patients with hypoglycemia whom the resected pancreas is normal. Hormone therapy m prove beneficial in patients who refuse surgical treatment in whom the operative risks contraindicate operation. Surgic excision of the tumor is, however, the treatment of choi because from 5 to 10% of the pancreatic adenomas a malignant. In addition, an untreated insulinoma may cau irreversible damage to the central nervous system by pr ducing progressive attacks of hypoglycemia.

Nocardiosis.—Nocardiosis is an actinomycotic infection caus by an aerobic genus of the family Actinomycetaceae. Nocard asteroides is the fungus most frequently responsible for th infection, which may vary from a frank abscess to a granulor atous lesion. The invading organisms may gain entrance the host by the routes of inhalation, skin penetration, ingestion. The clinical syndrome of nocardiosis is subject modification by host resistance, pathogenicity, and duration disease. Primary pulmonary infections are prevalent, bu external trauma can allow the disease to involve soft tiss and bone. The patient's course may be similar to that follo ing an emaciating illness, with local and blood-borne sprea of the infection. Treatment in the past was disappointing, bu excellent results were obtained in five patients treated b surgical intervention, chemotherapy, and an appropriate ant biotic. Adequate free surgical drainage or extirpation of th nocardiosis is essential for cure. The chemotherapeutic age of choice is sulfadiazine in adequate dosage combined with a antibiotic; both penicillin and oxytetracycline (Terramycin have proved effective in overcoming nocardial infections.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the merican Medical Association are not available for lending but can be plied on purchase order. Reprints as a rule are the property of authors can be obtained for permanent possession only from them. tles marked with an asterisk (*) are abstracted.

patients with coronary disease and 114 normal control persons with an average age of 49 and 46.5 years, respectively. Also reported are the responses to cigarette smoking in 82 patients with coronary artery disease and 118 normal control persons with an average age of 49 and 47.7 years, respectively. Men predominated in a ratio of 4 to 1 in the 200 persons subjected to the Master test and in a ratio of 5 to 1 in the 200 persons subjected to the smoking test. The ballistocardiogram deteriorated after exercise in 7.9% of the normal control persons and in 31.4% of the patients with coronary artery disease. The electrocardiographic response to exercise was positive by Master's criteria in 22.8% of the normal controls and in 50% of the patients with angina pectoris or remote myocardial infarction. The diagnostic margin of differentiation between persons with abnormalities and normal controls obtained by the stress of exercise was 4 to 1 by the ballistocardiograph and 2 to 1 by the electrocardiograph. The ballistocardiogram deteriorated after smoking a cigarette in 68% of the normal control persons and in 58.6% of the patients with coronary artery disease. The diagnostic margin obtained with the smoking test was 9 to 1. One-half of a milligram of nicotine base (nicotinic acid tartrate dissolved in 2 cc. of 35% alcohol) was administered sublingually to 10 persons in order to determine the importance of nicotine in the production of the smoking effect on the ballistocardiogram. The elicited ballistocardiographic alterations were similar to those observed after smoking in the 10 persons tested. The diagnostic value of the ballistocardiographic two-step test is limited. The difference between the incidence of positive tests in patients with coronary artery disease and in presumably normal controls is too small to be of importance in diagnosis. Contrary to expectation, only twice as many patients with coronary artery disease as normal control persons had a positive reaction to the two-step electrocardiographic test. Of all objective tests employed in the authors' study, the ballistocardiographic cigarette smoking test served best to differentiate patients with coronary artery disease from control persons. The causes of the changes in the ballistocardiogram after smoking are not known. It is suggested that the effect may be the result of nicotine action on the hypothalamic-posterior pituitary axis, with resultant release of vasopressin (Pitressin), which acts as a vasoconstrictor. This report should encourage further investigation of the effects of smoking and nicotine on the cardiovascular functions studied by analysis of the form of the ballistocardiogram rather than the routine use of the cigarette smoking test as a diagnostic procedure.

Incidence and Types of Heart Disease.—Of 34,342 patients seen at a Southern medical center between September, 1951, and February, 1953, 1,000 had organic heart disease. Of these 1,000 patients, 556 were men and 444 were women, 637 white and 363 Negroes. Hypertensive and arteriosclerotic heart disease were by far the commonest types; together they made up 77.9% of the entire series. The next in frequency were congenital heart disease, diagnosed in 7.2%, and rheumatic heart disease in 6.5%. Syphilitic heart disease occurred in only 2.3% of the patients. Comparison of these data with those by two previous studies made at the same medical center in 1927 and 1931 revealed that the incidence of organic heart disease is still greater in the Negro than in the white person, but much less so than 25 years ago. The incidence of hypertensive heart disease is approximately the same as before, but that of arteriosclerotic heart disease has increased. There has been a tenfold increase in the diagnosis of congenital heart disease associated with the greater awareness of congenital heart disease and improvement in diagnostic accuracy. Syphilitic heart disease has conspicuously decreased and is now infrequent. Rheumatic heart disease has shown little change in frequency, but there has been a slight decrease in bacterial endocarditis, apparently resulting from modern prophylactic therapy. Hypertension, as before, is commoner in the Negro than in the white, while arteriosclerosis is less frequent; however, the peak age incidence of hypertension seemingly occurs a decade later in each race than in the previous studies. There has been a striking increase in the diagnosis of angina pectoris, which, although commoner in the white, has been frequently recorded in the Negro.

Group Therapy with the Chronically Ill.—Group therapy meets successfully the needs of a chronic patient. The chronically ill patient lives in an egocentric world. He is assisted by nurses and attendants as his daily needs require. He is asked for nothing in return and easily grows accustomed to receiving with little thought for giving. Most of the children with which these authors are concerned had spent their entire lives in hospitals; they had had little normal experience. Common everyday objects were not perceived, and, when asked, the therapist was told that "potatoes grew mashed," horses "gave milk," and bread "came on a plate." Animals other than cats and dogs were strange. A program was organized that gave the children a dance-play experience. Dance movements were performed in wheel chairs and with the upper half of the body. When the children grew tired, they sang rounds, which were enjoyed enormously, and these required group discipline. A "painting day" was started, and some worked in other mediums. Little allowance was made for their disabilities other than to adapt equipment to fit their needs. The success and gratification resulting from their efforts has given rise to a healthy enthusiasm. Group therapy planning has also been introduced into craft work. No one of the patients can complete an entire project by himself, and the dependence on each other and cooperation within teams has made for a healthy working situation that is preparing them for future sheltered employment.

Mucopolysaccharides in Aortic Atherosclerosis.—Taylor points out that in recent years stress has been placed on the role of lipid deposition in the pathogenesis of atherosclerosis and that little attention has been paid to structural changes in the vessel wall. The present study deals with the human aorta, particular attention being paid to the relationship between the elastic fibers and the intercellular substance. The tissue examined was taken mainly from areas that showed no gross atheromatous plaques, other than occasional small fatty streaks. The tissue was obtained from routine necropsy material, 124 blocks being examined from 88 cases including all age groups. It was found that subendothelial, or so-called intimal fibrosis, was present regularly in adult aortas that appeared grossly normal or showed only minimal fatty streaking. It is also common in children. This fibrosis probably is initiated by lipid deposition. It may be confined to the intima, but frequently there is an associated degeneration of the inner layer of the media. In many cases, what at first appeared to be intimal fibrosis proved to be subendothelial fibrosis plus degeneration of the inner media. Medial degeneration is characterized by fragmentation and loss of elastic tissue with an associated accumulation of mucopolysaccharide, probably chondroitin sulfate. It is suggested that the abnormally large pool of mucopolysaccharide is derived from degeneration of elastic tissue of the media and may play a part in either the development of an atheromatous plaque or in hyalinization of the aorta.

Sterility of Surgical Linen.—According to Propst, little attention has been given to the sterility of surgical linen during operations, except to avoid contamination by direct contact with unsterile objects. Beck and Collette pointed out how easily wet drapes and gowns become contaminated. They proved that bacteria readily passed through two layers of wet cloth whereas two layers of dry cloth prevented such migration. Studies were made to determine (1) if bacterial migration through wet or dry linen is serious enough to warrant protective measures and (2) what materials and techniques can be used to offer maximal security. Experimental and clinical studies made at the Robert Packer Hospital proved that unprotected wet surgical linen furnishes a route of transmission of bacteria to wounds from unsterile areas. Because of the potential hazard, water and sodium chloride solution should be cautiously used in operating rooms, and wet areas should be considered contaminated and treated as such. Methods of eliminating or decreasing this type of contamination are discussed. One method (incorporating bactericidal agents into surgical linen) was intensively studied. The properties of an ideal bactericidal substance to use in such a situation are enumerated. Laboratory and clinical studies demonstrated the protective qualities of Roccal, a benzalkonium chloride, cationic quarternary compound, and hexachlorophene. Incorporating these agents into the final rinse in laundering surgical linen will decrease the possibilities of contamination from this source. Search for an ideal agent should be continued.

Primary Benign Liver Cell Tumors in Childhood.—Accor
to Christopherson and Collier, liver cell carcinomas in inf
and children are usually so advanced by the time the diagr
is made that surgical removal is not possible. The ave
duration of life after the onset of symptoms has been fo
to be about four months. There are, however, benign prin
liver cell tumors in which resection is possible with a
degree of success. The authors present the histories of t
children, aged 12, 7, and 13 years, respectively, in wh
primary benign tumors of the liver were successfully remo
In the first two, the diagnosis was hamartoma of the li
One of these was seen last 9 months after the operation, w
the child was asymptomatic; the other was without evide
of disease three years after operation. In the third, the op
tion was done in 1926, when the girl was 13 years old;
diagnosis was benign liver cell adenoma. This patient
25 years later, and autopsy revealed multiple polyposis
the colon, with two separate primary mucinous adenoca
nomas. The liver was largely replaced by metastatic mucin
cancer. Among other reported benign tumors in infancy
childhood, some were found at autopsy and others at the t
of surgical exploration. Of the latter, not all were resect
As might be expected, the precise classification and degree
benignancy or malignancy of certain of these tumors are o
to question. Benign primary liver cell tumors in infants
children include solitary liver cell adenomas, multiple ade
mas, and hamartomas. Cholangioma, a theoretical possibil
was not recorded in children. Solitary lesions have not be
accompanied by cirrhosis or other significant liver dise
and thus are amenable to surgical excision with a high deg
of success. Hamartomas are probably malformations rat
than true neoplasms or focal regenerative nodules and do
demonstrate the potentialities of malignant transformati
that adenomas do.

"Field Cancerization" in Oral Stratified Squamous Epitheliu
—Slaughter and associates point out that squamous cell,
epidermoid, carcinoma is the commonest cancer affecting t
human body. This tumor protoype may originate in mo
anatomic sites than any other form of carcinoma. It is t

usual cancer of the skin, lip, oral cavity, pharynx, larynx, bronchi, esophagus, anus, vulva, vagina, cervix, urethra, penis, and even bladder and renal pelvis. It may occur primarily or as a metaplastic variant in other organs. Since the behavior patterns of this morphological entity seem to have many similar characteristics in its differing locations and microscopic variations, detailed knowledge of the natural history of this disease is of importance. Oral squamous cell carcinomas were studied in 783 patients, and particular attention was given to their origin and manner of spread. Eighty-eight instances of independent multiple tumors were found, an incidence of 11.2%, which is far beyond the statistical possibility of chance occurrence. Microscopic evidence of multicentric origin was demonstrated by serial section in all excised tumors less than 1 cm. in diameter. Abnormal and hyperplastic, often atypical, epithelium was found to surround all oral cancers for varying distances. The authors were unable to derive any statistical estimate, but they believe "field cancerization" to be an important factor in recurrence or persistence of oral cancer after therapy.

Staphylococcic Gastroenterocolitis.—Fulminating diarrhea with a shock-like state was observed in six women and two men between the ages of 44 and 69 to whom various antibiotics, such as oxytetracycline (Terramycin), chlortetracycline (aureomycin), penicillin, streptomycin, chloramphenicol, and duracillin, in comparatively small doses were given before and after diversified operations, such as repair of diaphragmatic hernia, hysterectomy, vagotomy with gastrojejunostomy, closure of perforated duodenal ulcer, partial colectomy, release of post-surgical pelvic adhesions causing ileus, and cervical amputation with oophorectomy. Nausea and vomiting frequently preceded the onset of diarrhea by one or two days. With the beginning of copious watery stools, there was usually a sharp rise of temperature and pulse and respiration rates associated with a pronounced lowering of blood pressure. The uncontrollable diarrhea appeared in most patients on the second or third postoperative day and was sometimes still associated with nausea, emesis, and abdominal distention. Once vasomotor collapse was established, it seemed irreparable in all patients. Death occurred from the 3rd to the 11th postoperative day. The causative agent responsible for the acute inflammation of the gastrointestinal tract was presented by large masses of micrococci (staphylococci) *within* the desquamated or loosely adherent pseudomembranous exudate covering the mucous coat, particularly in the small intestine. The recent inflammatory reaction was in general restricted to mucosa and submucosa. Colonies of coagulase-positive hemolytic micrococci were recovered from the intestinal tract and/or from the lungs in five patients. The clinical course and anatomicopathological findings, based in particular on bacteria stains of the tissue sections from the gastrointestinal tract and including the recent degenerative changes in the adrenals and kidneys, suggested a severely toxic infection caused by massive micrococcic action on the gastrointestinal mucosa, but not a septicemic process. The micrococci grown on blood agar in the few instances tested were resistant against all the antibiotics used in these cases. The same clinicopathological syndrome with the same rapid fatal outcome and the same pathological, microscopic, bacterioscopic, and cultural findings was present in three recently observed cases. The micrococci grown from the intestinal tract and from the lungs in these cases were sensitive only to erythromycin, but not to the antibiotics administered.

Tonsils and Adenoids in Relation to Poliomyelitis.—Hayes states that during the summer of 1952 Delaware County, Pa., had a rather severe epidemic of poliomyelitis, with 190 cases and 15 deaths reported in a population of about 430,000. This means that 1 out of every 2,300 persons, or 44 in 100,000, in Delaware County contracted poliomyelitis. In the city of Philadelphia, there were 181 reported cases, with eight deaths, in a population of approximately 2 million. From a survey of the 190 cases, in 161 of which check-ups were made, and from review of the literature, Hayes concludes that there is a predisposition of the patient who has just had a tonsillectomy to contract poliomyelitis and that the bulbar type is two to three times as likely to occur in such patients. He, therefore, will continue his present policy of refraining from performing tonsillectomy and adenoidectomy within two months of the poliomyelitis season. It has been confirmed by countless surveys that in this area the months of greatest incidence are August and September, but in the epidemic under consideration one-fifth of the patients were stricken in October. An observer at the Department of Public Health of the City of New York stated that the safest time for tonsillectomies and adenoidectomies, as far as poliomyelitis is concerned, is January, February, and March. The author also shows that there is great hope that in the near future immunologic means will become available, which will greatly advance the combat of poliomyelitis.

Ringworm of the Scalp.—According to Robinson, tinea capitis is a benign but highly contagious disease that at the present time has reached epidemic proportions among school children, articularly in the eastern portion of the United States. Unfortunately, children who have this infection have been n to feel as outcasts in some schools, and a mental hazard been created. The physician who is charged with the sponsibility for the management of such a patient sh explain the nature of the disease to the parents as wel the type of treatment to be used and what may be expe of it. This is especially necessary in the event that epilation is to be used. All children who have tinea ca should be reported to the local health department, follow-up measures should be instituted to insure that remain under treatment until completion. School chil should be screened at periodic intervals, using the Wood l By this means infected children may be segregated referred to some proper treatment agency. The physician institutes treatment should insist on careful attention to pı health rules. To diminish the spread of the infection, chil should be warned not to exchange hats with other chil Barber shops should be made to abide by public health in the sterilization of all of their equipment, and chil attending movie houses should either wear hats or pla clean towel over the back of the seats. Immediately having a hair cut, the child should be taken home and g a thorough shampoo to wash out infected hair or spores.

Atomic Bomb Casualties.—This paper presents the obse tions of Japanese physicians on the atomic bomb casual of Nagasaki. There was an inverse relationship between mortality rate and the distance from the hypocenter of bomb explosion. Topography and structural shielding w determining factors in the mortality rate. Fatalities decrea greatly beyond the 1.5 km. zone. At this distance from hypocenter, wooden houses afforded some protection. D outs, although poorly constructed, were surprisingly effec in shielding the occupants. Within 1 km. of the hypocen the presence of thermal or mechanical injuries did not al the mortality rate, while beyond 1 km. the death rate highest in those persons who had received flash burns. Seven two per cent of the deaths reported from five hospitals curred in the first two week period, and the largest num of deaths on the 7th, 8th, 9th, and 10th days after explosion. Transportation over relatively great distan seemed to have deleterious effects. The survival of pers with burns was only slightly shorter than for those with ot external injuries, suggesting that radiation injury was a fac common to both. The incidence of flash burns was invers proportional to the amount of shielding; those persons concrete buildings had the lowest incidence and those in open the highest. Flash burns frequently involved extensi areas of the body, even at distances of 3 to 4 km. The was no significant difference in the extent of the burns betwe survivors and victims, again suggesting radiation injury as common factor. Persons who were inside of concrete wooden structures sustained more injuries than those wh were out in the open, the most frequent injury being fro flying glass. The symptoms of radiation sickness, such nausea, vomiting, diarrhea, fever, hemorrhage, epilation, an oropharyngeal lesions, are discussed in detail, particularl with regard to (*a*) distance from the hypocenter, (*b*) shielding and (*c*) time of onset. Hemorrhage and epilation are indexe of radiation injury.

Pathological Manifestations in Infant After Maternal Rubella.—Tedeschi and associates review the literature on the malformations occurring in infants after a maternal attack of rubella and cite the case of a 35-year-old woman who contracted rubella during the 16th week of pregnancy. A baby boy was delivered by cesarean section, three weeks before term. The infant had cataractous changes in the periphery of the lens of the right eye and acute panophthalmitis, including vascular thrombosis and infiltration of polymorphonuclear leukocytes of the eosinophilic type. It is suggested that lens protein released during the embryonic period played the role of a sensitizing factor. Renal changes were found that were mainly characterized by fibrosis and hyaline degeneration of the tufts and capsuls of the glomeruli. The authors recall that renal changes were observed also by Swan and others in infants born of mothers who had had rubella during pregnancy. They feel that the renal findings in the cases of Swan and those in the case reported here show that congenital glomerulosclerosis can also be found in infants in association with other postrubella manifestations, but this does not necessarily indicate that the virus of rubella was the cause of the glomerular changes. They may be nonspecific, late manifestations of the widespread attack of the virus of rubella on the tissues of the embryo.

Radioiodine Uptake in Hypothyroidism.—Radioactive iodine (I^{131}), generally in doses of 1 μc per kilogram of body weight, was injected intravenously into a vein of the arm or leg of 20 children between the ages of 2 months and 15 years with definite clinical and biochemical signs of hypothyroidism. Counts were made with a Geiger-Müller counter centered over the neck just above the episternal notch and held in close proximity to, but not touching, the skin. Counts were taken similarly with the counter placed over the anterior thigh a short distance above the knee at a point where the circumference was approximately that of the neck. Counts were taken immediately after the injection of I^{131} and at intervals of 10 to 15 minutes during the first hour. They were then repeated hourly until the 14th to the 16th and again at 24 hours. With the method described small amounts of radioiodine uptake that were anticipated could be demonstrated. It was assumed that persistence of radioactivity over the neck for several days or longer after it could not be detected elsewhere in the body is evidence that some thyroid tissue is present. Of the 20 patients, 14 had congenital hypothyroidism present at birth or beginning in early months of life and 6 had acquired hypothyroidism. Eight of the 14 patients with congenital hypothyroidism showed no measurable uptake of I^{131}, 4 showed small uptakes amounting to a retention over the neck of 3 to 16 counts per second, and 2 had normal uptakes of 90 and 95 counts per second. These observations suggest that in congenital hypothyroidism resulting from defective development of the thyroid there are differences in the degree of the defect. In the eight patients in whom there was no uptake of I^{131} pronounced symptoms of typical cretinism were present from birth or the early months of life. In the four patients who showed a slight uptake of I^{131}, history indicated a somewhat slower, more insidious onset of symptoms even though appearing during the first year of life. Of the remaining two patients with definite hypothyroidism who showed a normal uptake of radioiodine, one had a thyroid gland of normal size and the other a moderately enlarged gland. They lived in regions in which there was no likelihood of deficient iodine intake. The uptake of radioiodine in five of the six patients with acquired hypothyroidism indicated that small amounts of thyroid tissue were present, despite of the fact that the gland could not be palpated. The thyroid glands of these patients, however, were apparently incapable of responding to stimulation with thyrotropic hormone. The sixth patient had no uptake of I^{131} on the first test, but after injection of thyrotropic hormone showed a normal uptake. The hypothyroidism was of much shorter duration in this patient than in any of the others with the acquired type. It is possible that in some of these other patients with hypothyroidism of longer duration the initial failure may have been due to deficiency of thyrotropic hormone and subsequently the thyroid gland may have atrophied to a degree when it was not longer capable of responding to stimulation.

Hydrocephalus Treated by Arachnoid-Ureterostomy.—Arachnoid-ureterostomy or diversion of spinal fluid under pressure from the lumbar subarachnoid space to the urinary tract was carried out in 50 infants most of whom were between 3 and 6 months of age. In all but three patients, the left kidney was removed through a standard subcostal incision. Through a separate midline incision the spine and lamina of the second lumbar vertebra were removed exposing an area of dura about 1.5 cm. in length. A short incision was made in the dura and a pin point hole was then made in the protruding arachnoid and a polyethylene tube inserted through it as spinal fluid poured forth. The tube was then tunnelled through the paraspinal muscles to the perinephric space and introduced into the ureter for 3 to 5 cm. Three or four sutures in the margin of its lumen were used to pull the ureter over the plastic tube and secure it firmly to the fascia of the paraspinal muscles. There was only one postoperative death; this occurred in an infant in extremely poor general condition who died of postoperative aspiration pneumonitis on the seventh postoperative day. Follow-up revealed that 33 of the 50 patients are still alive, and satisfactory to excellent results were obtained in 31. At least 24 of these children appear to be entirely asymptomatic with normal or close to normal mental and physical development after periods of from a few months to over four years. Only one patient is grossly retarded to the point of needing institutional care. Results indicated that immediate and continuous reduction of spinal fluid pressure to normal can be accomplished by diversion of cerebrospinal fluid into the urinary tract. The complications of this procedure are three: (1) mechanical obstruction of the shunt that was observed in only a few patients and was always remediable; (2) meningitis, which occurred in 8 of the 50 patients postoperatively and was fatal in three; and (3) acute dehydration secondary to intercurrent infection because of unreplaced loss of fluid and electrolytes through the shunt that was fatal in about 10 of these patients.

Fatigue and Poliomyelitis in Mice.—In order to determine the effect of fatigue on susceptibility to experimental poliomyelitis, mice were forced to run in a revolving drum during the day preceding and for eight hours each day after the intracerebral injection of the Lansing strain of virus. Control animals inoculated at the same time with the same amount of virus were allowed to rest in their cages. In all experiments, the incidence of the disease as measured both by paralysis and by death was greater in the exercised animals than in the resting controls.

Five Years' Experience with Disulfiram.—Disulfiram (Antabuse) has proved excellent in the treatment of more than 2,000 alcoholic patients seen in the past five years in Copenhagen, Denmark. Proper administration of the drug will keep undesirable side-effects to a minimum. Of the many contraindications for use presented in the past, the only one remaining is marked cardiac decompensation. Disulfiram therapy is carefully planned to suit the physical and mental needs of each patient. Its ancillary methods include individual and group psychotherapy, alcoholics' club activities, and relaxation therapy. The drug may be given to sober patients on the first visit to the clinic and to intoxicated patients in a reduced dosage combined with an antihistaminic such as Promethazine (10-[2-dimethylamino-1-propyl]phenothiazine) and sodium chloride. This combination prevents nausea and vomiting while providing sufficient sedation. Furthermore, the symptoms of hangover and the craving for alcohol are considerably reduced, if not abolished, during the period immediately following. Patients with a low hyperactivity limen or a low amnesia limen should receive smaller doses from the beginning of treatment. When a well-adjusted maintenance dose of disulfiram is established, patients may ingest about 6 cc. of absolute alcohol and only a slight sensation of heat, redness, and acceleration of the pulse will result. The patient is told to moderate his drinking but total abstinence is not prescribed. It must be emphasized that disulfiram must never be given without the patient's knowledge and cooperation. The patient is carefully watched, especially during the first three months of treatment because the following effects of the drug are apt to increase during this period: fatigue during the daytime, sleepiness in the morning, headache and dizziness, reduced vitality and impaired memory, reduced libido and impaired potency, gastrointestinal disturbances, halitosis or metallic taste, shortness of breath, muscular sensations, and allergic skin phenomena. These symptoms are rarely persistent, and they can be easily controlled by reducing the dosage of disulfiram.

Congenital Absence of the Gallbladder.—Congenital absence of the gallbladder in a 62-year-old man was detected with the aid of cholangiography performed in the course of surgical intervention for dyspeptic symptoms and pain under the right costal arch radiating back and up to the right shoulder. Occasionally the patient had painful attacks of the type produced by cholelithiasis. He could not tolerate fat. Roentgenographic examination of the stomach and colon showed no signs of an abnormal condition. No filling was obtained by cholecystography. At operation, abundant adhesions made it difficult to approach the gallbladder. No well-defined gallbladder but a viscus-like formation was observed in this area. Cholangiography revealed that this viscus-like formation was a dilated and tortuous common bile duct united with a dilated hepatic duct. There was no gallbladder and no cystic duct, and no stones were detected. When reexamined four months after the operation, the patient still complained of persistent abdominal pains and reported that he occasionally had jaundice. Observations made in this case and cumulated evidence by other workers suggest the following conclusions: (1) operative cholangiography is the only reliable method for the establishment of a diagnosis of congenital absence of the gallbladder; (2) operative cholangiography is the only method available for excluding the presence of an intrahepatic gallbladder or remains of a gallbladder shrunken by cholecystitis; (3) the extrahepatic ducts should be drained for a long time after operation in cases of agenesis of the gallbladder causing severe symptoms; (4) agenesis of the gallbladder is often associated with adhesions in the upper part of the abdomen.

Effect of Desoxycorticosterone Acetate on Diabetic Ketosis.—It has been suggested that part of the insulin resistance and aggravation of the diabetic state that occurs during diabetic ketosis is related to the overactive adrenal cortex with consequent overproduction of 11, 17-oxysteroids. Since prolonged administration of desoxycorticosterone acetate (DOCA) can cause adrenocortical atrophy, experiments were made to evaluate the depressing effect of desoxycorticosterone acetate on the increased adrenocortical activity that occurs during diabetic ketosis. Adult male rats were made diabetic by the intravenous administration of alloxan (2,4,5,6-tetraoxohexahydropyrimidine). They were then placed in separate cages and fed on a relatively constant diet. All animals were tested for diabetes by the determination of blood sugar, and qualitative tests for glycosuria and urinary ketosis were also carried out. The diabetic animals were divided into three groups. The first group received no special treatment, and glycosuria and high blood sugar levels developed. The second group was controlled as well as possible with protamine zinc insulin. The insulin injections were begun 24 hours after alloxan was administered. These rats did not develop ketosis although some did show a moderate to severe glycosuria and a rather high blood sugar. The third group of diabetic rats received by subcutaneous injection 2 mg. of desoxycorticosterone acetate in 0.2 ml. of oil per day. (All other rats received similar injections of 0.2 ml. of oil per day as a control procedure.) The desoxycorticosterone acetate and oil injections were begun 24 hours after alloxan was administered. It was found that in rats with uncontrolled alloxan diabetes and ketosis, there was a marked increase in adrenocortical activity. Desoxycorticosterone acetate partially suppresses this increased adrenal activity but not to the same extent as insulin does. Desoxycorticosterone acetate administration to diabetic, ketotic rats causes a fall in blood sugar, which may be related to the partial suppression of adrenal activity and consequent decline in production of 11, 17-oxysteroids.

Serum Vitamin B_{12} Concentration of Patients with Megaloblastic Anemia.—Early studies showed the mean serum vitamin B_{12} concentration of normal subjects was about 320 micromicrograms per milliliter; the lower limit in normal subjects was about 100 micromicrograms per milliliter. The serum concentrations of patients with untreated pernicious anemia were low; the mean concentration was less than 40 micromicrograms per milliliter. Intramuscular injections of vitamin B_{12} produced a rise in the vitamin concentrations in the serum of patients with pernicious anemia from the low pretreatment levels to levels equal to or above normal. The duration of normal serum vitamin B_{12} levels and normoblastic hemopoiesis following single intramuscular injections of vitamin B_{12} in patients with pernicious anemia, which has a direct bearing on the treatment of this condition, was studied in 33 patients in relapse. The serum vitamin B_{12} concentrations of these patients rose from low pretreatment levels to normal after single intramuscular injections of from 20 to 1,000 mcg. of B_{12} and remained within the normal range for periods of from 2 to 98 days. The mean concentration in all the patients in each treatment group, however, although remaining within the normal range, fell below the mean concentration found in normal subjects within a few days after the injections. Hemopoiesis was normoblastic when the serum vitamin B_{12} concentrations were normal; when the concentrations were below normal megaloblasts reappeared in the marrow. Intramuscular injections of 40 mcg. of vitamin B_{12} every 10 days, or of 160 mcg. every 21 days, maintained the normal serum vitamin B_{12} level of most patients. These doses seem to be the minimum required for the treatment of patients with pernicious anemia in relapse. Much larger doses, up to 5 mg., should be given in the first week or two not only to [illegible] ly enough vitamin B_{12} for hemopoiesis, but also to replenish the greatly depleted tissue reserves. The serum vitamin B_{12} concentrations of a smaller group of patients with various megaloblastic anemias were not altered by treatment with folic acid or folinic acid. The amount of folic acid or folinic acid available for hemopoiesis, however, affects the relation between the serum vitamin B_{12} level and the type of hemopoiesis. The serum vitamin B_{12} levels remained low in patients with pernicious anemia in relapse, though hemopoiesis in their marrow rapidly became normoblastic while they were being treated with folic acid or folinic acid. The amount of vitamin C available may also be an important factor in the relation between the serum vitamin B_{12} levels and the type of hemopoiesis.

Vitamin B_{12} in Nutritional Macrocytic Anemia.—Vitamin B_{12} was given to 22 Indian patients with nutritional macrocytic anemia for the purpose of ascertaining its value in the treatment of that condition and incidentally of comparing its hematinic efficiency with that of folic acid and/or liver extract. Initial improvement was good in 14 patients, but the improvement was sustained and reached normal in only 5 patients treated with vitamin B_{12} alone. Folic acid was given after vitamin B_{12} in 14 cases with good response in 8, but again normal was attained in only 4. Crude liver extract was given to eight patients in whom the blood level had failed to reach normal after vitamin B_{12} and folic acid. In all but one the blood level then became normal. Indications are that both folic acid and vitamin B_{12} are valuable agents in the treatment of nutritional macrocytic anemia, which apparently represents deficiency of both these elements. Deficiency of folic acid is probably the primary and major factor, while that of vitamin B_{12} is probably the secondary factor in most cases. Patients with nutritional macrocytic anemia in different parts of the world may vary in their degree of deficiency of vitamin B_{12} and folic acid as a result of dietary differences. The response to therapy depends on both the absolute and the relative deficiencies of these factors, and this may account for the differences in response obtained by workers in various regions.

Porphyria in Surgery.—The occurrence of acute intermittent porphyria is reported in three surgical patients, one man aged 49 and two women aged 25 and 49, all of whom complained of severe abdominal pain and vomiting. The man had complained of acute attacks of abdominal pain for many years, and during one of these his appendix had been removed. He had been admitted to hospital frequently, and on the last admission his urine was tested for porphobilinogen and was found strongly positive. Further investigation demonstrated a pronounced impairment of liver function. The patient died, and necropsy revealed portal cirrhosis with massive ascites. For eight years during which the patient was supervised, he did not show evidence of impaired liver function. The conclusion was that the initial metabolic upset was acute intermittent porphyria and that the liver disease was secondary to his poor nutrition, to his high alcoholic intake, and to the ic effect of abnormal porphyrins. The younger woman exemplified the full-blown history of acute intermittent p phyria, a chronic illness featured by psychotic, gastrointestin and neurological symptoms, proceeding to inevitable dea In retrospect, it seems certain that she had an organic d denal obstruction that required surgical intervention. It see just as certain that the operative trauma elicited or contribu to a fulminating episode of neurological involvement. T other woman had undergone a gynecologic operation and hemorrhoidectomy that quite possibly were related to sym toms arising from porphyria. It is not suggested that pers suffering from porphyria could not have other organic disea The likelihood, however, that porphyria is the basis of symptoms, is overwhelming from the evidence presented these three patients and by others reported on in the literatu The typical patient with porphyria is a woman of early mid age, with a symptom complex of acute abdominal or neu logical disease, often without signs or laboratory and roent evidence to support an organic basis. A family and perso history of discord and mental upset is still more suggesti Psychotic behavior with hallucinosis is commonly seen. history of having passed dark or port wine urine and the fi ing of apparent urobilinogen on routine urinalysis make ten tive diagnosis possible. The specific test for porphobilino is then mandatory. The extreme probability of fulmination the acute episode following an operation must always remembered.

Pneumothorax-Pneumoperitoneum?—Of 275 patients, most them men between the ages of 20 and 40, with pulmona tuberculosis in whom 292 pneumothoraxes were induced, (21%) had minimal disease, 140 (51%) moderately advanc disease, and 77 (28%) advanced disease. Additional metho of collapse therapy were employed in 149 patients (54% The patients were followed up for 3 to 10 years. The resu of treatment on the basis of five year survival were co pared with those of treatment by bed rest alone derived fr the literature of past years in which collapse therapy w little used. A mortality rate of 2% among the author's patie with minimal disease and one of 8% among those with mo erately advanced disease are contrasted with a mortality ra of 23% and 53% respectively among the patients treated bed rest alone. The mortality rate in the entire series of 2 patients was 11%; the survival over five years of 89% the author's patients is considered very satisfactory. The i cidence of empyema among the author's patients was 6.2 as compared with an incidence of 12.6% among a large nu ber of patients with therapeutic pneumothorax collected fro the literature. This considerably reduced incidence of empye may have been obtained by observing certain precautions the selection of patients for pneumothorax and in their ma agement, which were not usually observed by the oth workers. The mortality from empyema in the author's patien was 37.5% as compared to 45% in those reported by oth workers. The mortality of 37.5% from empyema was onl 2.3% among all of the pneumothoraxes induced by the autho If all cases of empyema had been avoided and all these live saved by avoiding pneumothorax entirely, only 2.3% woul have been saved. The method of collapse used instead o "primary pneumothorax" in order to save this 2.3% would hav to at least equal pneumothorax in effectiveness and to hav no intrinsic mortality on its own. A survey of 2,646 cases o pneumoperitoneum collected from the literature showed tha this method of collapse was not free of mortality, whic might be as much as 1% over a five year period. Comparison of the effectiveness of pneumothorax with that of pneumoperitoneum as collapse measures was attempted by a stud from the literature of sputum conversion and cavity closure Pneumothorax gave superior results by a substantial margin although it appeared that more patients with advanced disease had been subjected to pneumothorax than to peritoneum. It is concluded that pneumothorax is, as a means of collapse, superior to pneumoperitoneum; with all its disadvantages pneumothorax as the primary procedure is still to be preferred for collapse therapy of most patients requiring such therapy provided that experienced surgeons are available who are willing to observe the author's precautions in the selection and management of the pneumothorax patients.

Effects of Radioiodine on Thyroid Function.—Myant says that although radioiodine has been used widely in thyrotoxicosis, little attention has been paid to the earliest changes in thyroid function. It is not known, for example, how soon the earliest effects can be detected, which of the various functions of the thyroid is first affected, or whether the first detectable changes are reversible. In the investigations reported here, an attempt was made to answer these questions by examination of four thyrotoxic patients selected for treatment with I^{131}. Serial radioiodine tests were made on these patients. At an early stage in the course of the treatment, both the uptake and secretion of radioiodine by the thyroid appeared to be inhibited. In one patient, the evidence suggests that the mechanism concerned in the secretion of hormone was more radiosensitive than that responsible for iodine uptake. In two patients there was partial recovery of thyroid function after an initial depression, while the treatment was still being continued and before there was evidence of clinical improvement. Then, when further therapeutic doses were given, thyroid function was again depressed and a clinical remission resulted. The total radiation dosage at which a depression of thyroid function could just be detected varied from about 500 to 10,300 roentgen equivalents in the four patients.

Bacteriology of Chronic Bronchitis.—A preliminary communication in May, 1952, showed that some organisms are distributed quite irregularly throughout the sputum of patients with bronchitis. In this paper the author describes the technique used in investigations on 54 outpatients and 14 inpatients with chronic bronchitis. A single culture from a specimen of sputum often fails to reveal all the species of bacteria present, even though the culture is made from a purulent part. A "specimen" of sputum, as used in this investigation, is defined as a portion of sputum expectorated by one bout of coughing only. Each specimen was expectorated into a sterile screw cap "universal container," to which was added about five times as much isotonic sodium chloride solution. The sputum was rinsed in the solution before being transferred to a sterile Petri dish. This dish was laid on a ruled grid of numbered squares. From a table of random numbers the first five numbers were selected that corresponded to numbers on the grid covered by the sputum. These indicated the sites from which cultures were to be made. Care was taken that the wire loop was not simply dipped into the sputum and withdrawn. The loop was used to extract a portion of sputum, which was then transferred to the side of the culture medium, where it was broken up before being spread over the plate. Each of the five cultures made from a specimen of sputum was subjected to "differential colony counting." The author feels that this technique of taking five cultures from one specimen is not practicable in a routine laboratory, and a method is required for liquefying the sputum without interfering with the viability of the organism. In this way a homogenous suspension could be prepared from which only one culture would reveal all the species of bacteria present. Such a method has now been developed by Rawlins. In some patients more than one specimen of sputum was required to reveal a "pathogen." Each of the 14 inpatients was producing consistently purulent or mucopurulent sputum. In 11 cases a "pathogen" was revealed in the first specimen: in 2 cases "pathogens" were found in the next specimen: and in the remaining case a "pathogen" (pneumococcus) was found only in the sixth specimen examined. Thus at least two and preferably more specimens should be examined. There is a significant association between pus in the sputum and the presence of potential pathogens, especially the pneumococcus and Hemophilus influenzae. Organisms of doubtful pathogenicity, such as Micrococcus (Streptococcus) viridans, nonhemolytic micrococci, and Neisseria catarrhalis, are not related to pus in the sputum.

Eosinophilic Granuloma or Hand-Schüller-Christian Disease? J. L. Keyzer and A. van der Velde.—p. 249.
*Occurrence and Treatment of Migraine in Children. J. C. de Wit.—p. 259.

Migraine in Children.—In the first part of this report de Wit is concerned with 74 children who had periodic attacks of headache and a history of one or several of the following factors: concussion of the brain, nasal adenoids, disorders of the nasal sinuses, visual defects, and allergic manifestations. Fifteen of these 74 children had family histories of migraine, and 6 of these 15 had allergic disorders. This incidence of allergy is not much higher than what can be expected in the absence of a family history of migraine. Gastrointestinal symptoms, with or without headaches, were observed in 4 the 15 children with a family history of migraine, and all 4 belonged to the allergic group. In the second part of this paper the author reports observations on 60 children belonging to 26 families with a history of migraine. Fifteen of these children had attacks of migraine before the age of puberty, but only 5 of these 15 retained their migraine attacks during puberty. Eight of the 45 children, who had been free from migraine during childhood, had their first attacks of migraine during puberty. Generally the attacks of migraine were the severer and more frequent, if the onset had been early. Prepuberal migraine occurred with the same frequency in both sexes, whereas more girls than boys had attacks of migraine during and following puberty. All children who had migraine attacks before puberty had a family history of migraine. Allergy does not play an important part in prepuberal migraine; the attacks differ from those in adults only by their greater frequency. Treatment with antihistamines proved most effective in children with migraine, and it appeared that the sedative effect of some of these drugs was not the decisive therapeutic factor. Early treatment is important.

Porphyrinuria in Exposure to Lead.—During the last two and a half years it has been the practice of Shiels and associates to determine the coproporphyrin content of all specimens of urine examined for lead in an attempt to assess the value of this very rapid test as an aid in the prevention and diagnosis of lead poisoning. The results of the examination of 279 specimens of urine from persons who had had various degrees of exposure are presented. There was a close correlation between the mean values of lead and of coproporphyrin in urine. Similar though not so close correlation existed between the stippled blood cell counts and the coproporphyrin content of the urine. The authors feel that from the point of view of routine control of employees exposed to lead hazards, the determination of the urinary coproporphyrin content has certain advantages over other tests, especially when a large number of persons have to be studied. The test can be performed in about 10 minutes, whereas urinary lead determinations may take several hours. Although a stippled blood cell count can be carried out in about 10 minutes for the actual count, the performance of a large number of these is tedious, and the preparation of slides, making of films, fixing and staining, washing and drying consume considerable time. One advantage of the stippled blood cell count is that the film provides a more or less permanent record. Whereas urine may be accidentally or purposely contaminated with lead, contamination with porphyrin is not likely, since only a very skilled person could accomplish this, without it being detected. The determination of coproporphyrin in urine is also helpful in establishing contamination with lead. In a case in point a high urinary lead value was obtained (0.6 mg. per liter) in a sample of urine. The coproporphyrin content was also high (0.7 mg. per liter), indicating that the patient had had considerable absorption of lead. The porphyrin in the urine is not stable under the influence of light, and hence the determination must be carried out shortly after the urine has been collected and on samples kept in amber-colored bottles and/or in the dark. The concentrations of coproporphyrin in the urine are not quite so closely related to the clinical conditions as are the stippled blood cell counts. It has also been pointed out that abnormal amounts of coproporphyrin in the urine indicate damage to the organism, whereas abnormal amounts of lead do not. Experience with over 2,000 analyses for lead in urine has indicated, however, that abnormally high values in the great majority of cases indicate damage to the organism. In the diagnosis of doubtful ses of lead poisoning stippled blood cell counts and the determination of lead in urine or blood should not be neglected, but rather should be combined with the coproporphyrin determination in the urine. Furthermore, the ratio of monocytes plus large lymphocytes to small lymphocytes should also be ascertained.

*Synthetic Antihistamines in Prophylaxis and Treatment of Post-Transfusion Reactions. C. Catalano.—p. 544.

Substitution of Esophagus with Isoperistaltic Colon.—In October, 1950, a 19-year-old woman accidentally swallowed sulfuric acid that severely damaged the esophagus. All attempts of endoscopic therapy failed, and roentgenograms revealed that the contrast medium stagnated in the oropharynx. Three months after the accident the patient could no longer take fluids and had to be fed through a gastric fistula. Attempts to dilate the esophagus by the retrograde approach through the fistula also failed. Two years later surgery was resorted to. In September, 1952, a laparotomy was performed to ligate and section the right ileocolic artery and to remove the appendix. A second intervention, which lasted seven hours, was performed about 20 days later. The middle colic artery and the right colic artery were ligated and sectioned. The ileum was severed about 5 cm. from the ileocecal valve. The cecum, ascending colon, and two-thirds of the transverse colon were mobilized, and an incision was made through the transverse colon slightly beyond the middle point. The segment that was to be substituted for the esophagus was about 45 cm. long. Its aboral end was sutured. The continuity of the alimentary tract was restored with an isoperistaltic ileotransversostomy. The distal part of the colon segment was anastomosed end-to-side to the first jejunal loop, and then the cervical stage of the intervention was begun. A long incision was made along the anterior margin of the left sternocleidomastoid muscle and the left omohyoid, sternohyoid, and sternothyroid muscles were resected. The sternal insertion of the sternocleidomastoid muscle was also resected. The esophagus, a hard string-like structure surrounded by extensive and firm adhesions, was severed about 3 cm. from the pharynx, and a rubber tube was introduced through the mouth and passed through the stump. The colon was then lifted retrosternally from the abdomen after the sternal apophysis had been resected. The laparotomy incision was sutured in layers. An end-to-side anastomosis was performed joining the cervical esophagus to the cecum, and the rubber tube was passed through the anastomosed area. The muscles that had been sectioned transversally were sutured and fixed over the new esophagus. Two drainage tubes were left in the cervical incision and were removed after four days. The immediate postoperative course was good. The cervical esophagus had a tendency to narrow, but gradual and painless dilatation was secured with common dilators in about 30 days. The patient was able to take fluids and semifluid food. But shortly thereafter severe postprandial symptoms developed that were probably due to exclusion of the stomach from the alimentary tract. A third operation was performed in January, 1953, to form a colon-gastrostomy in addition to the colon-jejunostomy that had been formed during the second intervention. A side-to-side anastomosis was performed joining the lower portion of the colon, which served as esophagus, to the stomach. The postprandial symptoms disappeared, the general condition of the patient began to improve, and on March 1, 1953, the gastric fistula could be closed definitively. At the time of writing, the patient was well and was able to eat any food. Roentgenograms indicated that the new esophagus was functioning well.

Synthetic Antihistamines in Post-Transfusion Reactions.—Synthetic antihistamines have been used to prevent or treat post-transfusion reactions when a hypothesis was advanced that these reactions may be of allergic origin. The author studied the effects of intravenous administration of antihistamines in 220 direct and indirect transfusions at the clinic of the University of Palermo from April, 1950, to May, 1952. The patients who received an average of 250 cc. of blood or plasma were divided into four groups, and three antihistaminic preparations were used. The first group of 57 patients was given the antihistamine preparation as soon as the reactions appeared (15 to 30 minutes after the transfusion). They occurred in 64% of the patients but disappeared within four minutes after the administration of the drug. A second group of 105 patients was given the antihistamine preparation immediately before and after the transfusion and again 15 minutes later. Blood and plasma to which the antihistamine had been added were given during surgery to 22 and 16 patients respectively. Coagulation was prevented by means of Novotrans, a hyposulfite. A fourth group of 20 persons received the antihistamine 15 minutes after the transfusion. The best results were obtained in these patients with a 37% decrease in the incidence of reactions. The same incidence of reactions was found in those to whom the antihistamine was given concurrently with blood or plasma during surgery. But the good effects in these patients were ascribed mainly to the desensitizing action of the hyposulfite. The prophylactic effect of the antihistamine preparations varied according to the time at which they were administered. The intravenous administration of the preparations did not cause side-effects. The results seem to confirm the theory of the allergic pathogenesis of post-transfusion reactions.

*Combined Administration of Penicillin and Streptomycin in Urology. F. Strähuber.—p. 1012.

Oxytetracycline in Severe Surgical Inflammations.—Oxytetracycline (Terramycin) is the antibiotic with the widest spectrum of efficacy in vitro. It was used in the treatment of 54 surgical patients. There were 32 severely ill patients with peritonitis. Severe diffuse infection of the abdominal cavity had occurred in 14 of these 32 patients and was due to perforating appendicitis in 6, perforating Meckel's diverticulum in 1, postappendectomy infection in 1, perforating gallbladder in 2, perforating gastric ulcer in 2, and perforative peritonitis secondary to prolonged constriction of intestine in 2. The suppurative peritonitis that was caused by Escherichia coli, Proteus, or hemolytic streptococci was controlled in all 14 patients with continuous infusion of 2 gm. of oxytetracycline for one to eight days followed by oral administration in tablets of 1 gm. of the drug in 24 hours for 3 to 11 days. Sixteen of the 32 patients had localized peritonitis due to perforating appendix in 8, perforating gallbladder empyema in 4, perforating ulcer in 2, and secondary to operation for carcinoma of the colon and of the stomach in 2; all these patients were given oxytetracycline first intravenously and then orally, and except for one patient with insufficiency of duodenal stump after primary resection of the stomach for a giant callous perforating duodenal ulcer, all the others made a complete recovery. The lives of some of the patients with diffuse or localized peritonitis, who were too ill to be operated on, were saved by the oxytetracycline. Two patients with large appendical abscess were therapeutic failures. Highly satisfactory results were obtained in patients with acute phlegmonous infection, particularly in those caused by anaerobes.

Combined Administration of Penicillin and Streptomycin in Urology.—Pasimycin, an antibiotic compound containing 1 gm. of dihydrostreptomycin sulfate and 400,000 units of penicillin, was given prophylactically to 20 patients who underwent radical prostatectomy. One-half of the original dose, i. e., 0.5 gm. of streptomycin and 200,000 units of pencillin, was administered four times at 6 hour intervals in 24 hours. A continuous minimum blood level of streptomycin can be obtained *only with injections* repeated at least every six hours. Concentrations in the urine of 500 to 1,000 gamma per cubic centimeter were obtained with the six hourly injections of 0.5 gm. of streptomycin. Primary healing of the operative wound was obtained in 12 of the 20 patients. A urinary fistula due to catheter disturbances or insufficient suture of the bladder developed in eight patients, but healing of the operative wound occurred after mild inflammation in five, while suppuration occurred in only three patients. Satisfactory wound healing thus occurred in 75% of the patients operated on while receiving combined penicillin-streptomycin therapy. There was not a single case of severe ascending urinary infection. Of 20 patients who underwent radical prostatectomy without prophylactic treatment with antibiotics primary healing of the wound occurred in 4, and in additional 4 patients healing of the wound occurred after mild inflammation associated with a temporary urinary fistula. The ratio of 75% of satisfactory healing of the wound with antibiotic prophylaxis as compared to 40% without it, suggests the use of large doses of streptomycin combined with penicillin for operative prophylaxis, although the small number of cases does not permit definite conclusions. Shortening of the average postoperative hospital stay by three days was an additional advantage of the combined antibiotic therapy. It was continued for only 96 hours because bacteria that would have remained in the wound after this period would have become resistant and further continuation of the treatment might have masked, but not prevented, the impending suppuration of the wound. The expenses of the suggested prophylactic treatment seem to be justified, since antibiotic treatment after prostatectomy will be required in most patients because of threatened ascending urinary infection.

Psychic Factors in Pathogenesis of Myocardial Infarction.—The symptoms of myocardial infarction in the first two patients were preceded by anginal attacks of more than ordinary duration. One, a 63-year-old man, had one attack of angina of 15 minutes' duration 12 days before the onset of infarction. Several days later, he had a similar attack of the same duration, and then after several milder and shorter attacks, the myocardial infarct developed. This and another patient had these anginal attacks only about two weeks before the infarction, and it was especially noteworthy that the first anginal attack followed psychic tension and emotional stress the cause of which persisted. The author presents histories of several other patients in whom myocardial infarction developed after worry about difficulties had persisted for some weeks, and the infarct itself appeared during a violent emotion caused by the difficulties. The seriousness of the difficulties as well as the psychic predisposition of each patient may have contributed to the damaging effects. The predisposition may be congenital or result of previous experiences or of somatic disease. It is well known that the development of hypertension often influences the degree of emotional upset, and myocardial infarct often develops in hypertensive patients. Several brief case histories are presented to illustrate this connection. Other patients complained of great fatigue some months before the occurrence of the infarct, and it is not improbable that although these patients did not as yet have angina, their fatigue may have been due to some insufficiency in their coronary circulation, which also may perhaps increase emotional upset. The relationship between infarction and [illegible] psychological factors as a rule remains unrecognized [illegible] a special inquiry is made with regard to this possibility.

*Mesenteric Vascular Occlusion. H. M. Karn.—p. 289.

Mesenteric Vascular Occlusion.—Karn presents histories of 9 patients with mesenteric vascular occlusion observed at the Dunedin Public Hospital over the past four years. Patients may present as medical or surgical cases or as cases without clear diagnostic features. Medical cases may occur in patients with auricular fibrillation receiving digitalis or quinidine, patients with endocarditis, and patients with coronary infarction of some weeks' duration in whom a mural thrombus has suddenly detached. There may be diarrhea and melena, and some may recover on the establishment of a satisfactory collateral circulation. Surgical cases may occur in patients with intestinal obstruction sent into hospital for observation. There may be severe abdominal colic, fecal vomiting, abdominal distention, and constipation. In rapidly fatal cases with some undiagnosed abdominal catastrophe, abdominal colic and vomiting are followed by sudden pallor, shock, and death. In cases with no clear diagnostic clinical features there may be abdominal colic with melena, with or without abdominal distention and tenderness. Roentgenography with barium and sigmoidoscopy shows nothing abnormal; some patients are subjected to laparotomy in order to exclude a neoplasm and evidence of intestinal infarction may be found. In the medical cases, which have been correctly diagnosed, gastrointestinal suction should be established to prevent distention. Blood or blood substitutes should be given intravenously to combat shock. Anticoagulants should be administered for several days. Patients in whom the mesenteric vascular occlusion is encountered at laparotomy as a surgical emergency require resection of the infarcted bowel with end-to-end anastomosis and the immediate administration of anticoagulants to limit further local thrombosis. Resection with a temporary double-barrelled enterostomy by the Paul-Mickulicz technique has likewise proved successful.

*Treatment of Pulmonary Tuberculosis in Patients with Leprosy. S. de Oliveira Lima and M. Fontes Magarão.—p. 397.
Early Results of Intracavitary Isoniazid in Association with Monaldi's Aspiration. E. Rizzo and R. Costa Carvalho.—p. 441.

Tuberculosis in Patients with Leprosy.—Leprosy is rare in pulmonary tuberculosis whereas the latter is frequent in patients with leprosy. Out of 1,019 patients with leprosy observed by the authors in a period of four years, 119 (11%) had pulmonary tuberculosis, with or without cavitation. Of 106 patients, 60 had pulmonary cavities and 46 did not. All of the patients had the dietetic hygienic regimen and streptomycin, which was given intramuscularly in daily doses of 0.5 gm. per injection up to a total dose of 15 or 30 gm. for each series. Twenty-two patients with cavities had collapse therapy, by pneumothorax or pneumoperitoneum, with cure in 2 cases, improvement in 8 cases, and death in 3. The condition did not change in one case and became worse in 8 cases. One patient without cavities had pneumoperitoneum with consequent cure. In the 38 patients with cavitation who did not have collapse therapy the figures were as follows: Cure in 2 cases, improvement in 9, death in 15, and 12 cases either unchanged or worse. In the 45 patients without cavities who did not have collapse therapy the figures were as follows: Cure in 38 cases, improvement in 3, death in 2, and unchanged course in 2. The authors obtained remarkably good results in 21 out of 22 patients with leprosy and pulmonary tuberculosis from administration of isonicotinic acid hydrazid. The results are recent and conclusions cannot be reached. They conclude that streptomycin is of value with simultaneous good results on both pulmonary tuberculosis and leprosy. The mucosal complications of leprosy improve simultaneously with the clinical symptoms, roentgen signs and bacteriological findings of pulmonary tuberculosis. The drug is specific in tuberculoid forms of leprosy. It causes disappearance of small pulmonary cavities. The occurrence of streptomycin-resistanc of tubercle bacillus does not call for discontinuance of th drug for as long as the patient maintains his body weight an the general condition, the symptoms, roentgen signs, and bacteriological findings show improvement. Collapse therapy is th necessary treatment of pulmonary tuberculosis with cavitatio in patients with leprosy.

Search for Koch's Bacillus by Inoculation of Guinea Pig in Curre Practice. F. Tison.—p. 831.

Endobronchial Perforations of Lymph Nodes.—Bronchial pe forations of the lymph nodes that coincide with the onset chronic phthisis are exceptional. At a later stage, lesions ma appear in the lymph nodes and lead, notably after the ag of 50, to fistulas that are usually unipolar, but sometim bipolar or multipolar. In the latter case, the fistulas a bronchial or esophagobronchial. That there is no pathogen connection between perforations of the lymph nodes an primary infection is the opinion of the authors. Their opinio is based on their observations of the differences in time an place of appearance of these two kinds of lesions. The anteri segment of the upper lobes is the preferred area of dischar of pus from the lymph nodes while primary infection nev occurs here. It is felt that the contrary doctrine of Schwar that primary infection is a lesion of bronchial aspirati caused by the discharge into the bronchi of pus from fistul of the lymph nodes, is incorrect as far as modern Weste Europe is concerned because it is based on observations Near Eastern peoples who have not been exposed to the di ease for as long a period and have, therefore, acquired little no immunity to it.

Rivista di Neurologia, Naples

Catatony Due to Bulbocapnine: Electroencephalographic Study. L. Sin and G. Tonini.—p. 269.

Neurological Symptoms in and Treatment of Periarterit Nodosa.—The neurological symptoms present in patients wi periarteritis nodosa are important diagnostic factors, althou they are often underestimated or misinterpreted. These sym toms may involve either the central or the peripheral nervo system. Peripheral neuritis is the commonest. Sometimes, whe the central nervous system is involved, the symptoms may typical of acute vascular disease with hemiplegia, aphagi conjugate deviation, and Jacksonian or generalized convulsi attacks. Papilledema may be present in some instances an the meningeal syndrome in others. Extrapyramidal sympton and lesions of the bone marrow are rare. The patient unde goes states of confusion, loss of consciousness, depressi states, and frequent changes of mood. Peripheral neuritis wi intense pain is present in the initial or early phase of th disease. It may occur in the form of a mononeuritis multiple involving most frequently the median, ulnar, radial, and tibial nerves, or it may be a symmetrical progressive polyneuritis that involves the nerves of the lower extremities. The progression of the lesions is not, however, uniform and may cease at any stage. There may also be partial remission. Differential diagnosis should be made between the neuritis present in other infectious diseases such as diphtheria, typhoid, malaria, and endemic encephalitis. Biopsy has diagnostic value only when it is positive. In many instances in which biopsy did not indicate disease, the disease was confirmed at autopsy. Periarteritis nodosa may be acute with a sudden onset and severe impairment of the general condition and the central nervous system. Death in these cases is due to severe renal insufficiency and heart failure. Chronic periarteritis nodosa may last for many years with persistent symptoms and periods of remission and exacerbation. The main anatomic alteration is a localized exudative necrotic arteritis. There is at first necrosis of the media extending toward the intima in the arterioles and the adventitia in larger arteries. Then cellular infiltration and proliferation of the connective tissue occur, nodular aneurysms appear, the proliferation of the intima sometimes obliterates the lumen and granulomatous tissue is formed. A temporary remission may then follow. Corticotropin and cortisone have been used to treat patients with the disease since its lesions resemble closely those of collagen diseases and since it was thought to be of allergic origin. Subjective improvement with gain of appetite and strength, return of temperature to normal, and changes in the neurological symptoms have been reported together with a decrease in the number of eosinophils, diminished sedimentation rate, and increased elimination of the 17-ketosteroids. But the symptoms have reappeared after the therapy was discontinued. The authors are of the opinion that this treatment is mainly symptomatic and doubt whether it can arrest the process of the disease.

*Prolonged Treatment of Rheumatic Disease, and Particularly of Rheumatism of the Heart, with Cortisone. L. Villa, C. B. Ballablo and G. Sala.—p. 806.

Pathogenesis of Rheumatic Granuloma.—According to von Albertini, Aschoff's nodules represent a type of granuloma that is characteristic of rheumatism and should be considered as microscopically specific. The primary alteration of the tissues that precedes the occurrence of Aschoff's nodules has not been fully elucidated; a primary necrosis of muscle besides a fibrinoid necrosis of the connective tissue seems likely. The cell reaction of the granuloma serves the absorption of necrotic masses; it arises from the large basophilic cells of the granuloma that are to be considered as histiocytes. After the absorption, they seem to be transformed into the so-called "Anitschkow's cells." The term cardiohistiocytes is suggested for these cells that, however, are not myocytes since they are not limited to the myocardium but occur also in the endocardium and epicardium. They were observed in various abnormal conditions of the heart such as myocarditis, endocarditis, and pericarditis of various etiology (rheumatic and subacute bacterial endocarditis), also in experimental wound healing and in healing of cardiac infarcts. These cells, therefore, are not cause specific, not even of rheumatism, but are specific of the heart only. The authors' studies thus did not reveal any new facts from the etiological point of view. They did not provide any argument against the concept of Micrococcus (Streptococcus) infection, although the possibility of a contributing allergic factor must be admitted. It is quite possible that rheumatism too may be an allergenic infectious disease.

Cortisone in Rheumatic Disease.—Cortisone combined with procaine and crystalline penicillin, phenylbutazone (Butazolidin), aminopyrine, and sodium salicylate was used in the treatment of 41 patients with rheumatic disease. Eighteen of these were in the acute stage and did not present any cardiac lesions; nine did not show clinical signs of cardiac involvement but erythrocyte sedimentation rate, polysaccharides, and antistreptokinase power of the serum were increased, and there was dysproteinemia. The remaining 14 patients had clinical signs of involvement of the heart, and the laboratory findings were the same as in the 9 patients. Although the number of patients treated was small and the follow-up period short, the authors feel that the results obtained justify the following conclusions: the possibility of a preventive action with respect to cardiac involvement may be reserved to a small number of patients if treatment is instituted at the onset of the rheumatic attack, but is limited exclusively to the duration of this attack. On the contrary, a progressive course of the disease with involvement of the heart may be limited or arrested in a large number of patients by the institution of a prolonged treatment using the following schedule: a course of 300,000 units of procaine penicillin, 100,000 units of crystalline penicillin, and 2 to 3 tablets each containing 25 mg. of cortisone acetate daily for 10 days, followed after a five day rest interval by a course of 300,000 units of procaine penicillin, 100,000 units of crystalline penicillin, and 2 to 3 tablets each containing 0.2 gm. of phenylbutazone daily for 10 days; after a second rest interval of five days, the 10 day course of penicillin-cortisone treatment is repeated and is followed after a third five day rest interval by a course of 300,000 units of procaine penicillin, 100,000 units of crystalline penicillin, and 2 to 3 suppositories of 0.5 gm. of aminopyrine daily for 10 days; a fourth five day rest interval is followed by a course of 8 to 10 gm. of sodium salicylate daily for 10 days. The therapeutic action of this combined treatment should be recognized as definitely more effective than and superior to other methods of prolonged treatment tried previously. The prolonged treatment of cardiac involvement in the chronic stage of the rheumatic disease allows for the limitation and occasionally for the disappearance of signs of a progressive course. Cortisone therapy is effective in attenuating the general symptoms in patients with rheumatism of the heart in whom clinical signs are manifest and the disease progresses rapidly (the term progressive rheumatic carditis has been suggested for this condition). In most of the patients, improvement continued for the duration of the treatment and ceased with discontinuation of the treatment; in certain cases, however, improvement continued provided prolonged treatment was given for a sufficiently long period. Concomitant signs of cardiac decompensation should not be considered as an absolute contraindication to cortisone therapy. Although occasionally it may aggravate the signs of decompensation, it may exert a favorable influence on the circulatory condition in certain cases. Cortisone therapy should be omitted in patients with grave functional symptomatology and the dose of the drug should be regulated in other patients according to the favorable or unfavorable first signs of its effect on the particular condition of each patient.

BOOK REVIEWS

Peptic Ulcer: Pain Patterns, Diagnosis and Medical Treatment. By Lucian A. Smith, A.B., M.D., M.S., Assistant Professor of Medicine, Mayo Foundation, Rochester, Minnesota, and Andrew B. Rivers, M.A., M.D., M.S. Foreword by George B. Eusterman. Cloth. $12.50. Pp. 576, with 208 illustrations. Appleton-Century-Crofts, Inc., 35 West 32nd St., New York 1, 1953.

This new book is intended to aid in the diagnosis of peptic ulcer with a new approach to pain patterns involved in the various types of ulcer and their complications. The authors, with their additional contributors, have the extensive experience of the Mayo Clinic as their source of material. They have summarized the records from the Mayo Clinic and the recent literature on the subject. The basic discussion of the anatomy of pain, which is divided into somatic and visceral components, is both clear and detailed. There is an excellent discussion of the pathological anatomy—gross, microscopic, and roentgenologic. With each type of ulcer and complication of ulcer there appears a profuse illustration of the pain pattern, with numerous case histories to illustrate each type followed by a differential diagnosis.

Diseases of other organs anatomically related to the upper gastrointestinal tract are also differentially diagnosed from peptic ulcer. A discussion of the various complications includes recommended therapeutic routines. C. A. Good, roentgenologist of the Mayo Clinic, has contributed an excellent, profusely illustrated chapter that shows the roentgenologic findings in the various types of ulcer and complications. There is a long discussion of the methods of treatment used at the Mayo Clinic, followed by an appendix containing the various diets and other portions of medical management. It is noted that the patients are still awakened for milk and cream at midnight, 2:00 a. m., and 4:00 a. m. (pages 484, 485, and 501). Only atropine and methantheline (Banthine) bromide are discussed as anticholinergic agents, although these have been supplemented by more recent drugs. To prevent and control fecal impaction, the authors recommend a glycerin suppository or the retention of 3 oz. (85.05 gm.) of mineral oil overnight, and, in some instances, several "sudsy" enemas and "bulk" laxatives (page 498).

The physical examination of the entire body, outlined on page 146, seems too detailed for this type of book. The type is large and easy to read, but the numbers used for bibliographical references are too large and sometimes tend to interrupt the trend of thought. This is an excellent reference book to be used in the differential diagnosis of various types of abdominal pain. Peptic ulcer is discussed from a viewpoint different from that in any other current book. It is recommended especially to gastroenterologists and to anyone who treats ulcers in the course of his practice.

European Seminar and Lecture Course on Alcoholism. Sponsored by Royal Danish Government in cooperation with World Health Organization and United Nations, Copenhagen, 22 October–3 November 1951. Paper. Not for sale. Pp. 121, with 8 illustrations. Regional Office for Europe of World Health Organization, Palais des Nations, Geneva, 1953.

This book is a compilation by Professor E. M. Jellinek, consultant on alcoholism to the World Health Organization, of the seminars and lectures on alcoholism. The seminars and lectures were presented by experts on the medical, biological, and social aspects of alcoholism from Austria, Belgium, Denmark, Finland, France, Germany, Norway, Sweden, Switzerland, United Kingdom, and Yugoslavia. The book presents, in five sections, an up-to-date, factual, and clear summary of our knowledge and experience with the complex problem of alcohol addiction: (1) the physiological action of alcohol, (2) the causes of alcoholism, (3) the clinical findings and special features of alcoholism, (4) medical treatment of alcoholism, (5) the prevention of alcoholism and public care of alcoholics. Some European countries are far ahead of others in medic and public (social-economic) service to alcoholics. Unfort nately, this valuable publication is not for sale, but copi may be obtained from the European office of the World Heal Organization by medical libraries and health institutions.

The Diabetic Neuropathies. By Joseph I. Goodman, M.D., Siegfri Baumoel, M.D., Leonard Frankel, M.D., Louis J. Marcus, M.D., a Sigmund Wassermann, M.D. Publication number 151, American Lectu Series, monograph in Bannerstone Division of American Lectures in Enc crinology. Edited by Willard O. Thompson, M.D., Clinical Professor Medicine, University of Illinois College of Medicine, Chicago. Clo $4.75. Pp. 138, with illustrations. Charles C Thomas, Publisher, 301-3 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Lt 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toro 2B, 1953.

This monograph is a new addition to the American Lectu Series, a long line of current and fairly complete revie of medical subjects by recognized authorities. It was produc by a team from Mount Sinai Hospital in Cleveland, amo whom are students of neurology, peripheral vascular disea internal medicine, and diabetes. The authors have analyz the findings in their own series of 261 patients with diabet 62% of whom were judged to have neurological manifes tions, and compared them with those reported by other autho As such, the monograph is a source of much information clinical value. The experienced clinician will detect so apparent faults of interpretation, but these are of minor i portance compared to the faithfulness with which fact observations have been recorded. Illustrations and tables few in number, but organization is good, references to p tinent literature are generous, and the mechanical work ma tains the high quality characteristic of this publisher.

Textbook of College Hygiene. By Oliver E. Byrd, Ed.D., M.D., P fessor of Health Education, Stanford University, San Francisco. Clo $4.50. Pp. 443, with 26 illustrations. W. B. Saunders Company, 218 Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., Lond W.C.2, 1953.

Teacher's Manual for Use with Textbook of College Hygiene. Oliver E. Byrd, Ed.D., M.D., F.A.P.H.A. Paper. Pp. 43. W. B. Saund Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaft bury Ave., London, W.C.2, [n.d.].

Unique in its approach, this textbook is based on care surveys to determine the health interests and needs of colle undergraduates, rather than presenting what the author thir such a group should be told. After his studies, Byrd select the 30 chief subjects as chapter topics. The resulting book perhaps not far from what the average well-qualified hea educator would settle on without the aid of such a surv but, at the same time, there would appear to be added assurance that the material has been well chosen.

Presumably the author began the book with the subject which greatest interest was expressed and proceeded on a descending scale with subsequent topics. It is an interesting commentary on present interests that the first chapter deals with health in marriage, the second with pregnancy and childbirth, and the third with infant and child care. The next four chapters concern emotional and mental problems. From this point on, a large number of topics are covered, including nutrition, care of the teeth and eyes, communicable diseases, tuberculosis, heart disease, cancer, high blood pressure, accident prevention, atomic energy, and the problems of medical care. Excellent discussions are provided on tobacco, alcohol, and narcotics.

Another good feature of the book is a small manual of suggestions on teaching methods, this being available to teachers on request. It is well illustrated, and at the end of each chapter are questions to assist in review of the material, as well as references for additional reading. This book should be of great value in any college health education class.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically stated.

A Guide to Human Parasitology for Medical Practitioners. By D. B. Blacklock, C.M.G., M.D., D.P.H., Director of Sir Alfred Lewis Jones Laboratory, Freetown, Sierra Leone, West Africa, and T. Southwell, D.Sc., Ph.D., A.R.C.Sc., Director of Fisheries to Governments of Bengal, and Bihar and Orissa. Revised by T. H. Davey, O. B. E., M.D., D.T.M., Professor of Tropical Hygiene, Liverpool School of Tropical Medicine, University of Liverpool. Fifth edition. Cloth. $5.50. Pp. 228, with 123 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

Although it is partly implicit in the title, it should be stated that this book cannot be considered on a par with currently available comprehensive textbooks on the subject. It is intended primarily to serve as a physicians' manual for laboratory identification of human parasites. The new edition includes short comments on prevention applicable to each parasite but does not provide information on treatment. The material is presented under the names of the parasites, which are grouped into chapters in accordance with classical zoological subdivisions. A chapter on spirochetes may be questioned as properly belonging within the scope of animal parasitology, and the authors indicate that they should not be classified with protozoa. On the other hand, the book omits certain parasitic diseases frequently included in more extensive works on parasitology. The anatomic diagrams of parasites are clear and resemble drawings found in standard books on zoology. The magnification or actual size of the drawings is not stated in several instances. A section of diagrams to illustrate the life histories of parasites provides a convenient summary of the salient features involved. A general index at the end, with main entries in boldface type, increases the usefulness of the book. It can be recommended for beginning students of the subject and to physicians who may require a guide to laboratory diagnosis for rural practice.

Textbook of Medical Treatment by Various Authors. Edited by D. M. Dunlop, B.A., M.D., F.R.C.P., Professor of Therapeutics and Clinical Medicine, University of Edinburgh, Edinburgh, L. S. P. Davidson, B.A., M.D., F.R.C.P., Physician, H. M. The Queen in Scotland, and Sir John McNee, D.S.O., M.D., D.Sc., Physician, H. M. The Queen in Scotland. Sixth edition. Cloth. $9.50. Pp. 1023, with illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 & 17 Teviot Place, Edinburgh 1, 1953.

The rapid advances in therapeutics during the past few decades have made frequent revisions essential to the continued usefulness of any textbook of medical treatment. The sixth edition of this book appears only 14 years after the initial edition, which was published in 1939. New authors have completely rewritten the chapters on tuberculosis, tropical diseases, nutritional diseases, nephritis, psychotherapy, and care of the aged; new chapters on chemotherapy, poisons, rehabilitation, and the treatment of malignant disease appear for the first time in this edition. Some revision has been made in every chapter, bringing all abreast of current developments. As implied in the title, the objective of the book is to provide the student and practitioner with specific information and instructions as to "the management of the case" rather than with theoretical aspects of drug action. As a result, there is a fund of detailed, practical advice on general measures for the care of the patient as well as on specific drug therapy. Although thoroughly up-to-date as far as the newer methods of treatment are concerned, the authors have consistently outlined conservative therapy well suited to help the practitioner maintain a cautious and skeptical attitude toward new and untested drugs.

As is to be expected in a book of this sort, whose 29 chapters were written by 28 different authors, the quality is not entirely uniform. More space is devoted to such remedies as mild mercurous chloride (calomel) and turpentine and to the virtues of fresh air and of keeping bowels open than one is accustomed to seeing in American texts these days. This does not seem to be a result of undue emphasis, however, but rather an absence of the deemphasis of some of these older measures that has occurred in this country with the rise of "scientific" medicine. The typography is good, and there is a thoroughly adequate index. On the whole, the authors have produced a book that once again demonstrates the respect with which the English language is treated by medical writers in the British Isles. Although it is evident that the book is intended primarily for English practitioners (with frequent references to rationing and to the difficulty in obtaining certain drugs in England, more emphasis on care of the patient in the home rather than in the hospital, and use of British proprietary names), its sane, balanced, and specific advice to the physician should be just as welcome here as on the other side of the Atlantic.

The Sulphonamides and Antibiotics in Man and Animals. By J. Stewart Lawrence, M.D., M.R.C.P., and John Francis, M.Sc., M.R.C.V.S., Professor of Preventive Medicine, University of Queensland Veterinary School, Brisbane. With assistance of Arnold Sorsby, M.D., F.R.C.S., Research Professor in Ophthalmology, Royal College of Surgeons & Royal Eye Hospital Surgeon, Royal Eye Hospital, London, and Philip G. Scott, F.R.C.S., Consultant Surgeon, E.N.T. Depart., Royal Devon and Exeter Hospital, Exeter. Second edition. Cloth. 42/. Pp. 482, with 39 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1, 1953.

This new and greatly enlarged edition brings the subject matter up-to-date. The chapters on mode of action, drug resistance, the chemistry, bacteriology, pharmacology, and other aspects of both the sulfonamides and antibiotics are especially clear and complete. There is an extensive bibliography. The book covers all aspects of actions and uses of sulfonamides and antibiotics in man and in animals. If it has weaknesses, they are due to the broadness of its scope. For example, in discussing gonorrhea, the statement on page 196 that this "disease may eventually be completely stamped out" seems a little too enthusiastic; on page 198, the absolute injunction that routine tests of cure with the introduction of sounds should be made in every case of gonorrhea would not be accepted by 99% of American physicians; the suggestion made on page 214 for the dosage of streptomycin in tuberculosis is not in line with current thought; and, little mention is made of bacitracin, which is becoming an increasingly useful antibiotic. These errors of commission represent differences in opinion and do not detract from the general excellence of the publication, which can be recommended to students and physicians alike as the most useful book yet published in the field of sulfonamides and antibiotics.

The Year Book of Medicine (1953-1954 Year Book Series). Edited by Paul B. Beeson, M.D., et al. Cloth. $6. Pp. 736, with 127 illustrations. Year Book Publishers, Inc., 200 E. Illinois Street, Chicago 11, 1953.

This volume, the first of the current new series of the "Practical Medicine Year Books," contains abstracts of selected reports published in medical periodical literature between May, 1952, and May, 1953. The abstracts cover the field of internal medicine during that period and are divided into individually edited sections on infections, the chest, the blood and blood-forming organs, the heart and blood vessels and the kidney, the digestive system, and metabolism. Each abstract has a reference to the journal in which the complete report was published. The references are tabulated by means of superscript numbers, 1 through 9, repeated in that sequence throughout the text, and thus do not indicate the total number of abstracted articles either in the sections or the entire book. This scheme avoids the use of more than a single digit for each reference. When they consider them appropriate, the editors have appended bracketed comments to aid in the interpretation of the abstracted reports. These comments often are critical as well as constructive and increase greatly the value of the book as a review of the important recent literature. Subject and author indexes are included at the end. The typography, binding, and small over-all size are designed for convenience and ready reference. The book will be highly useful to all physicians who desire to keep informed of the significant advances in both experimental and clinical medicine.

History of the Second World War: United Kingdom Medical Series. Editor-in-Chief: Sir Arthur S. MacNalty, K.C.B., M.D., F.R.C.P. **The Emergency Medical Services. Volume I: England and Wales.** By Lieut. Colonel C. L. Dunn, C.I.E., I.M.S. Cloth. 50s. Pp. 460, with 51 illustrations. Her Majesty's Stationery Office, P. O. Box 569, London, S.E.1, 1952.

Civil defense received its first full scale test in modern times in World War II. The editor of this volume had practical experience as a regional hospital officer during the first two years of the war. This book on the planning, organization, and operation of the Emergency Medical Services of England and Wales is one of a number of publications dealing with the medical aspects of the history of World War II that are being compiled under the guidance of Sir Arthur S. MacNalty. The evolution of the Emergency Medical Services in Great Britain during World War II represented an extraordinary development in civilian medicine. This book presents in a concise manner the functions and work of these services in providing medical care as adequate as was possible under the conditions existing in England and Wales during the period 1939 to 1945. Furthermore, a careful interpretation of the activities of these Emergency Medical Services is enlightening in retrospect relative to the development of the National Health Service in Great Britain. Because of the wealth of material relating to organizational planning and the subsequent operational activities that stemmed from such planning, this book should be of special interest to all who are concerned with the broad aspects of medical planning for civil defense.

Clinical Unipolar Electrocardiography. By Bernard S. Lipman, A.B., M.D., Instructor in Medicine, Emory University School of Medicine, Atlanta, and Edward Massie, A.B., M.D., F.A.C.P., Assistant Professor of Clinical Medicine, Washington University School of Medicine, St. Louis. Second edition. Cloth. $6.50. Pp. 309, with 260 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1953.

The first edition, published in 1951, was limited to the subject of unipolar electrocardiography and did an excellent job in making a difficult subject clear and understandable. In this edition sections on cardiac arrhythmia, myocarditis, congenital heart disease, hyperventilation, and the two-step (Master) exercise test have been added. This new material has increased the size of the book until it can scarcely be considered a monograph any longer but is approaching the size of a textbook. Very little change has been made in the original section of the book. The bibliography contains no reference later than 1950. Over 100 pages of illustrative electrocardiograms are included. This book is recommended for reference for cardiologists and internists with a special interest in diseases of the heart.

Textbook of Histology. By José F. Nonidez, D.Sc., and William F. Windle, Ph.D., Sc.D., Scientific Director, Baxter Laboratories, Inc., Morton Grove, Ill. Second edition. Cloth. $9.50. Pp. 528, with 326 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; 95 Farringdon St., London, E.C.4, 1953.

Since the first edition of this book appeared in 1950, about three years after the death of the senior author, the present revision has been undertaken entirely by Windle. The book is designed primarily to acquaint beginning students with the fundamentals of histological structure and function. Controversial discussions are avoided for the most part, and the bibliography consists only of brief lists of collateral readings at the end of each chapter. The illustrations are numerous, clearly labeled, and excellently reproduced. The subject matter is clearly presented, and there is no small type. The material covered by this text, supplemented by classroom guidance, should be entirely adequate to meet the needs of first year medical students. The book is, however, too limited in scope and dogmatic in approach to serve as a review or a reference text for the advanced student.

Group Work with the Aged. By Susan H. Kubie and Gertrude Landau. Cloth. $3.50. Pp. 214. International Universities Press, Inc., 227 W. 13th St., New York 11, 1953.

This book is an account of experiences in organizing and working in a recreational day center for the aged. The setting described is the William Hodson Community Center, a unit of the Department of Welfare of New York City. It was started nine years ago as a pioneering experiment in social welfare. From an uncertain beginning, the project has grown in stature and significance and now may well serve as a model for the many similar units that are springing up throughout the country. The authors point out that one of the major problems of the aged is their progressive isolation from the community and friendly human contacts. Centers such as the one described are designed to meet to some extent the human need for social living. By means of the illustrative cases and excerpts from what must have been a daily diary, the authors succeed in bringing the reader into the community center to see for himself how it functions. The authors' background and training in social work and psychiatry is evident from their intelligent and enlightened comments on the human problems encountered. The volume is exceedingly well written and interesting. It should not be missed by anyone who has anything to do with groups of older people. More than that, the authors demonstrate that older persons have in many respects the same potentialities for development as children, if they are cared for and handled with some of the same skill, patience, and kindness.

Surgical Pathology. By Lauren V. Ackerman, M.D., Professor of Surgical Pathology and Pathology, Washington University, School of Medicine, St. Louis. Cloth. $14.50. Pp. 836, with 913 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

Although much work has no doubt gone into the preparation of this book, the result is disappointing. The reader is confused because of the numerous ambiguous statements, inconsistencies, and dogmas. One is at a loss to explain why a book on surgical pathology would attempt to censure the modern surgeon with such a statement as "'Can I get away with this operation?'" The reviewer feels certain that the modern surgeon, who truly lives up to that appellation, is primarily interested in the patient and not in surgical exhibitionism. Again one is at a loss to understand another innuendo aimed at the surgeon, when on page 18 the statement appears that technical dexterity is "a fairly common commodity." Such ungracious statements are pointless and surely do not fall into the realm of surgical pathology.

Numerous contradictions are noted throughout the text, the most blatant example of which is the following: The author correctly states that the surgical pathologist "must have a rich background of clinical medicine," but chapter 2, which deals with dermatopathology, has been assigned to a nonmedical colleague. This is difficult to comprehend. Another example of confusing contradiction is to be found in chapter 11, dealing with the liver. On page 380 this sentence is noted: "We have found aspiration biopsy to be definitive in making a diagnosis not only of a primary malignant neoplasm of the liver but also of metastatic carcinoma and melanocarcinoma (Fig. 434)," but on page 386 one finds the following sentence: "Resection of a single metastatic lesion or resection of metastases in continuity of primary tumor (cancer of the stomach, cancer of the large bowel) may yield satisfactory palliation." Surely aspiration biopsy can not determine whether the metastatic lesion is single or multiple, or whether or not it is resectable. Exploratory laparotomy only can determine these facts, and, if this is contemplated, why should the patient be subjected to the biopsy? Although Ackerman claims that the risk of such aspiration is "slight," he nevertheless includes a reference that records 14 deaths from this procedure. One wonders at the number of such fatalities that are not reported.

Dogmatic statements are dangerous particularly when they appear in a textbook that is written for medical students. The author asserts that frozen sections of hyperplastic lymph nodes "should not be difficult to interpret." Many qualified pathologists would disagree with such an assertion because of the difficulties that frequently are encountered in differentiating a hyperplastic lymph node from a lymphoblastoma, not only on frozen but also on paraffin sections. A discussion of the esophagus appears in chapter 9. The author includes esophageal diverticula that occur in the lower third of the esophagus in the same category as those that appear in the region of the hilum of the lung. He therefore refers to both of these as traction diverticula and says that they are associated with inflammatory changes in regional lymph nodes. This is incorrect because those diverticula that are found in the lower third of the esophagus (epiphrenic) are of the pulsion variety and have nothing to do with lymphadenopathy. In this same section the statement is made that carcinoma does not arise within such diverticula. This is certainly erroneous. Diverticulosis and diverticulitis are again discussed under the heading of "Large Bowel." In neither of these parts was there any space alloted to the important physiopathology that pertains to diverticula. The specific role played by stasis should have at least been mentioned.

This book has not kept abreast with recent trends since no mention is made of the truly modern version of radicalism in so-called radical mastectomy. This includes a dissection of those nodes that course along the internal mammary artery and are surely important to the pathologist. Current literature has no paucity of material dealing with chronic relapsing pancreatitis. Although Dr. Ackerman has one reference to this condition in the bibliography, a discussion of it is lacking. This malady certainly is as important as some of the rare conditions he describes. Although clinicians and pathologists now avoid the misused and abused misnomer of chronic cystic mastitis in favor of the more acceptable term mammary dysplasia, "Chronic Cystic Mastitis" is the heading of a section of this work. In the discussion that deals with tumors of the salivary glands, papillary cystadenoma lymphomatosum (Warthin's tumor) is considered. The author remarks that this tumor does not become large. Although such tumors are rare, the reviewer has seen in his own clinical material a Warthin's tumor that was so large that it elevated the lobule of the ear. The appearance of such definite statements is clinically misleading and at times dangerous, especially if one is called on to prognosticate the course of the lesion.

Gonorrheal infection of the fallopian tubes is still an important part of any textbook on pathology. The medical student as well as the physician will repeatedly refer to textbook's for an adequate description of this condition. The following is the entire space alloted to it. "Tubular infection in gonorrhea is common and leads to progressive obliteration of the lumen by progressive destruction of the epithelium. The microscopic changes which are present are those of chronic inflammation." If one wished to acquire information regarding this condition, he would again have to refer to another textbook. The following meaningless sentence constitutes the entire discussion of the clinical findings in acute cholecystitis. "In acute cholecystitis the clinical symptoms and signs are those of an acute surgical condition." Such a statement is better left unwritten than to be presented in such an erratic fashion. Although there is much didactic material in this work that could be of great value, it has been lost by poor writing, poor editing, or poor proofreading. The illustrations have been beautifully reproduced, and the references that appear at the end of each chapter constitute the best part of the book.

Standard Methods of Clinical Chemistry. Volume I. By the American Association of Clinical Chemists. Editor-in-Chief: Miriam Reiner, Director, Chemistry Laboratory, Gallinger Municipal Hospital, Washington, D. C. Cloth. $4.50. Pp. 142, with illustrations. Academic Press, Inc., 125 East 23rd Street, New York 10, 1953.

In its constitution, written in 1948, the American Association of Clinical Chemists pledged to standardize and codify chemical methods of analysis used in clinical laboratories. This volume is the first in a series compiled to meet this objective. It contains instructions for performing the commonest routine laboratory tests; specialized subjects will be treated in the later volumes. Each method first was tested in the laboratory of the chemist submitting it. Then it was sent to checkers who retested it for "validity and practicality" on normal and pathological specimens. While the nature of the individual test has somewhat influenced the style in which the chapters are written, all consider the scope of the test and give the names and affiliations of the submitters and checkers of the test; references to the original literature; the underlying principle; and methods of preparing the reagents, collecting and pretreating the samples, and performing the assays. Usually, calculation of result's, discussion of normal and pathological values, and bibliographies are included. The introduction outlines the role of the clinical chemist in a hospital laboratory.

The particular substances for which tests are included in this volume are amylase, bilirubin, calcium, carbon dioxide (titrimetric and volumetric methods), chloride, total and free cholesterol, creatinine, glucose (two methods), lipase, alkaline and acid phosphatase, inorganic phosphate, blood proteins, sodium and potassium (by flame photometry), urea nitrogen, and uric acid. The other tests are for prothrombin time and thymol turbidity. The book is beautifully printed, adequately indexed, and sturdily bound to stand the constant use it should receive at the hands of chemists, technicians, and clinical pathologists.

Keep Your Voice Healthy: A Guide to the Intelligent Use and Care of the Speaking and Singing Voice. By Friedrich S. Brodnitz, M.D. Introduction by Olin Downes. Cloth. $3.50. Pp. 234, with 17 illustrations. Harper & Brothers, 49 East 33rd Street, New York 16, 1953.

The subtitle of this book informs the reader that it is a guide to the intelligent use and care of the speaking and singing voice. The author's approach to voice production is derived from a comprehensive understanding of artistic problems as well as from an extensive experience with singers and public speakers. In general, he advocates no narrowly restricted method. The nontechnical language of the book is designed to make readily understandable to the lay reader sections on the anatomy and physiology of the vocal structures, their acute and chronic diseases, their medical treatment, and the various disturbances of voice and speech that can be remedied. Because it is the first such book written for the general public, it should prove especially useful to voice teachers, salesmen, actors, lecturers, businessmen, and those concerned with radio and television.

Plant Diseases in Orchard, Nursery and Garden Crops. By Ernst Gram and Anna Weber. Edited and adapted by R. W. G. Dennis, Ph.D. Translated from Danish by Evelyn Ramsden. Cloth. $18.50. Pp. 618, with 360 illustrations. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1953.

This translation of the second edition of a book by Danish plant pathologists of international reputation is the first edition in English. The English editor has made the book more useful by including references to English work in plant pathology. In addition, brief reference is made to plant diseases known in Britain that are not met with in Denmark and hence were not described in the Danish text. The first section of the book is devoted to general principles dealing with the nature of plant diseases. The next three sections are concerned with the diseases of individual plants and crops. These are arranged under the headings: "Tree and Bush Fruit," "Vegetables and Herbaceous Fruit," and "Ornamental Plants and Trees." The last section deals with control measures. The value of the book is greatly enhanced by the illustrations, which have been chosen to facilitate recognition of the diseases rather than to illustrate microscopic characteristics. This book fills a definite gap in our literature on plant diseases and is a practical aid in recognition and treatment of plant diseases. It differs from other English books on plant diseases, which approach the subject from an academic viewpoint. This book should prove very valuable to growers, nurserymen, horticultural research stations, agricultural colleges, and anyone who has an interest in gardening.

Atomic Medicine. Edited by Charles F. Behrens, M.D., Rear Admiral, MC, U. S. Navy. Second edition. Cloth. $11. Pp. 632, with illustrations. Williams & Wilkins Co., Mt. Royal and Guilford Aves., Baltimore 2, 1953.

The first edition of this book appeared in 1949; the present edition contains new material on medical aspects of radioactive isotopes, high voltage acceleration, and radiation protection. It offers three detailed introductory chapters on the principles of atomic structure and ionizing radiation. These are followed by a magnificently illustrated chapter on the atomic bomb in action. The remaining chapters take up in detail the biological effects of atomic warfare and the steps to be taken by way of defense. The two chapters on survival methods in atomic disaster and on the design and operation of laboratories employing radioisotopes in medical research are of direct practical concern. There is a wealth of technical information in the form of tables and illustrations; the bibliography is good; and an ingenious index refers to decimally numbered sections instead of pages. The book will interest every medical reader.

QUERIES AND MINOR N

SURGICAL TREATMENT OF CORONARY ARTERY DISEASE

To the Editor:—*I have had two episodes of coronary occlusion within the last three years. Every cardiologist I have consulted has a different opinion as to the benefit of surgery for this condition. I have not practiced for about a year. Fortunately, outside of extreme fatigue I have had no other startling symptoms. I would like to have your opinion of surgery for this condition and the results as compared to conservative medical treatment.*

M.D., Wisconsin.

Answer.—The surgical treatment of coronary artery disease has been investigated by Beck and his associates in Cleveland since 1932. A large amount of surgical and physiological experimentation has been done on this subject. Two operations, the Beck 1 operation and the Beck 2 operation, were developed. These operations protected the heart against the destructive effects following experimental occlusion of a major coronary artery. Either of these operations saved the life of the animal and also saved myocardium after a major coronary artery was ligated. These operations were applied to about 125 patients who had severe coronary artery disease. In 81% of the patients who could be evaluated, the clinical result was excellent or good. The definition of "excellent" is "no pain, no medication, and return to former employment." The definition of "good" is "occasional pain, occasional medication, and return to former employment." The mortality in the last two years has been about 20%. The risk of the operation depends largely on the type of case accepted for operation. A number of patients with large infarcts and enlarged hearts were accepted for operation. These patients were in desperate condition and were bad risks for any operation. It is the condition of the heart rather than the operation that determines mortality. The medical mortality in these patients is high. If the patient has a good enough heart to go through the operation, the probability is that he will receive a good result. Operation is indicated for patients whose lives are threatened by a "mechanism death." The myocardium is good enough to function for a period of years but a "dry area" destroys the coordinated beat. Surgical methods can prevent these "dry areas" from developing by producing a more even distribution of the blood that goes through the diseased coronary arteries and also by adding additional blood to the heart from outside sources. The operation should be done early in the course of the disease rather than late. The operation cannot stop the occlusive process in the arteries, nor can it undo the degenerative changes in the heart muscle after the arteries have been occluded. It can protect the heart if it is applied before the occlusion strikes. The proper timing of the operation in reference to the course of the disease is a problem for the internist and the surgeon. The facts established by experimental investigation are being applied to the patient with coronary artery disease. It is important for the internist to become familiar with these facts and to appraise their value. His reluctance to do so may retard the proper treatment of his patient.

INTRAVENOUS DIGITALIZATION

To the Editor:—*When intravenous administration of digitalis is indicated, is lanatoside C or ouabain generally preferable? Are there any conditions in which one might be preferable?*

Leonard Casser, M.D., Cresskill, N. J.

Answer.—Apart from the fact that a smaller dose of ouabain is required, the chief difference between the drugs is
that ouabain has a shorter laten
within 5 minutes and becoming m
whereas lanatoside C requires two
produce its effects. Ouabain has
European and Latin American card

EPINEPHRINE AND CARDIOVASCULAR

To the Editor:—*Is administration of epineph*
lin) contraindicated for typical attacks of br
in patients who have hypertension, coronar
or arteriosclerotic heart disease?

Charles H. Codelle, M.D.,

Answer.—The pressor and cardiac excitato
epinephrine make it necessary that it be used wi
cardiovascular disease; however, the need for its
weighed against any possible harm. Often, a
hypertension who is having an acute attack of
increased blood pressure during the attack, wh
becomes lower after relief of the dyspnea with

Human blood or its derivatives are rarely considered
therapeutic measure for measles, and certainly would not
administered as a remedy for German measles, a mild
ease. When convalescent serums were used extensively, blo
was usually drawn from donors 10 days to 2 weeks after
onset of the disease if the infection was uncomplicated.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless sp[illegible]lly so stated in the reply. Anonymous communications and queries o[illegible]ards cannot be answered. Every letter must contain the writer's [illegible], but these will be omitted on request.

RCUMCISION

THE EDITOR:—*I have been requested to circumcise a Jewish infant in accordance with the ritual practice that precludes the use of sutures. The postoperative bleeding is supposed to be controlled by applying an astringent dressing and a tightly fitting band or tape around the penis. I refuse to perform such operation, on the ground that control of hemorrhage without sutures is unsafe. I would like to know whether performance of circumcision without the use of sutures is to be viewed as a surgical operation that cannot be approved of from a medical standpoint.*

Samuel Newman, M.D., Danville, Va.

This inquiry was referred to two consultants, whose re- ective replies follow.—ED.

ANSWER.—It is considered good surgical practice to avoid e use of sutures on any oozing surface when bleeding can e controlled easily by means of pressure; however, in the ent that active arterial bleeding is present, it becomes man- atory that such bleeding be controlled by ligation.

ANSWER.—It seems better to answer this inquiry from a rely surgical standpoint, excluding any religious relation. When doing a circumcision it is highly desirable to clamp nd tie all bleeding points and to place sutures to control leeding and approximate the epithelial edges. If sutures are ot taken for this purpose, the wound will heal by granula- on tissue and thus require much longer time for complete ealing. Obviously, it is dangerous to stop the bleeding by pplication of any band or ties around the penis.

FLUSHING OF FACE AND NECK OF WOMAN

To THE EDITOR:—*A 43-year-old woman had an artificial menopause when she was 38 because of radium implantation to control menorrhagia. Since then she has taken 1.25 mg. of estrogen (Premarin) daily. Her chief complaint is a permanent flush of the neck and the face of three months' duration. Examination shows a red flush of the face and neck not unlike that seen in chronic alcoholism, with numerous telangiectases. The patient does not drink or smoke. Her blood cell count is normal. Urinalysis and physical examination show nothing abnormal. There has been no undue exposure to the sun. Could the flush be due to (1) the prolonged intake of estrogen, (2) an early sign of lupus erythematosus, or (3) a psychosomatic manifestation? There is a basis for the latter.*

M.D., Pennsylvania.

ANSWER.—The flush of face and neck is probably not due to the estrogen administration. Actually, one would expect that the estrogen would relieve, at least partially, the flushing, since it does control the tendency toward capillary dilatation and fragility. Lupus erythematosus involves more than just a flushing. There is possibly a psychosomatic factor involved in this flushing of the face and neck. Women are especially prone to this distribution of flushing. It is not uncommon for a woman at her first examination in a physician's office to exhibit flushing of the face, neck, and chest.

HIRSUTISM DURING PREGNANCY

To THE EDITOR:—*A woman, 30, had her first child two years ago. During that pregnancy hair developed on her face, anus, and chest some of which disappeared after pregnancy. This patient would like to have a second child, but is afraid she will become more masculine in appearance. She has been to Boston for consultation but was not given any definite answer.*

Robert H. Goldman, M.D., Leominster, Mass.

ANSWER.—F. J. Stoddard (*Am. J. Obst. & Gynec.* **49**:417 [March] 1945) found reports of only five cases of hirsutism occurring in pregnancy in the literature. In at least two of the five, marked facial hair growth developed in three successive pregnancies. In one the hair fell out each time four to six months post partum, and in the other the hair disappeared about five weeks post partum. Other authors have reported a tendency toward alopecia in pregnancy. Similar conflicting findings have been observed in experimental animals. Stoddard reports two cases of hirsutism in pregnancy. In one patient the excessive hair growth appeared in the first pregnancy on the face, arms, legs, and back. At about eight weeks post partum she had a menstrual period. Shortly thereafter while taking a bath she noted that rubbing on the skin surface with a rough turkish towel removed the hair. She completed the hair removal that afternoon, and her hirsutism disappeared. The same events were repeated precisely one and a half years later. The patient is now free from excessive hair, and there are no masculine characteristics. In the second case the hair disappeared five months after labor. The inquirer may tell his patient that the hirsutism will most likely return in the next pregnancy but the excessive hair growth will be the only masculine characteristic that will develop. The hair should disappear after delivery.

CEREBRAL PALSY AND PREGNANCY

To THE EDITOR:—*A woman, aged 28, is a victim of cerebral palsy. Her husband has the same disease. She came to see me months ago complaining of sterility, and after treatment became pregnant. I am unable to find any reference in the literature to pregnancy and cerebral palsy or vice versa. Shall I permit her to deliver vaginally or should a cesarean section be done?*

M.D., New York.

ANSWER.—In all likelihood the patient's neurological condition will not influence the course of her labor. If she has a normal pelvis and the pregnancy proceeds uneventfully, she should be allowed to go into labor spontaneously and to deliver as naturally as possible. It may be necessary to terminate the labor by episiotomy and use of outlet forceps. Spinal anesthesia should be avoided. Abdominal delivery should be considered only for obstetric indications that may arise.

URINARY TRACT INFECTION

To THE EDITOR:—*A man has a urinary tract infection that is reported to be due to a "yeast-like, fungus organism." The urine is loaded with white blood cells. This followed cystoscopy for hematuria that revealed severe hydronephrosis on the left and hydroureter. There are five or six diverticula of the bladder, one of which appears to be larger than the bladder itself. Chlortetracycline (aureomycin), oxytetracycline (Terramycin), sulfisoxazole (Gantrisin), sulfonamides, methenamine mandelate (Mandelamine), and nitrofurantoin (Furadantin) have had no effect on the pyuria. The patient is comfortable and working, and I feel that sterilization of his urine would be adequate therapy. Could you offer any suggestions?*

Burchard S. Pruett, M.D., St. Louis.

ANSWER.—The "yeast-like, fungus organism" probably is not the cause of the urinary infection in this case and is secondary to inadequate drainage from the bladder. Although no statement is made regarding the existence of residual urine, the presence of five or six diverticula of the bladder is usually accompanied by a variable amount of residual urine. It would be difficult, if not impossible, for any urinary antiseptic to overcome infection in the presence of residual urine in the bladder. Cystourethroscopic examination is necessary to determine the existence of obstruction at the bladder neck. If obstruction is evident, it usually can be corrected by transurethral resection. If not, a careful search should be made to exclude neurogenous etiological factors. If the cause for any inadequate drainage of the bladder is corrected, the diverticula might contract. If they do not, diverticulectomy may be indicated. Yeast-like fungi usually belong to the genus Candida, the commonest form of which is C. albicans (monilia). These organisms have a low pathogenicity. They are not affected by any of the drugs mentioned. Should they persist in spite of the corrective measures suggested, lavage of the bladder with a solution of gentian violet might be tried.

BURNING SENSATION IN MOUTH

To the Editor:—*A man, aged 60, complains of constant burning in the mouth since 1944. This burning sensation resembles that following unusually hot drinks. There is no seasonal or daily variation, and it is not relieved by cold drinks, local anesthetics, or antiseptics. The patient is edentulous, but the condition is not affected by the presence or absence of full dentures. There is slight aggravation following the smoking of one pack of cigarettes a day. There is no visible change in the mucosa. The area of involvement includes the buccal and gingival surfaces without extending to the tongue. Please advise concerning diagnosis and treatment.* *W. L. Janus, M.D., Riverside, Calif.*

Answer.—A burning sensation of the tongue and oral mucosa is relatively common and may be related to systemic disease such as diabetes, vitamin A deficiencies, pernicious anemia, and decreases in salivary output. These are usually accompanied by visible signs of irritation of the mucosa. One of the changes associated with aging is dry mouth, associated with loss of keratinization of the mucosa and accompanied by stickiness of saliva that leads to mechanical irritation. The irritation may not cause gross changes in the mucosa. In some patients a burning sensation of the mucosa is psychogenic. The fact that the sensation in this patient is not relieved by local anesthetics would indicate that the pain is not a localized reaction to irritation but results from some conditions that the patient interprets as a burning reaction.

PENICILLIN REACTIONS

To the Editor:—*In* The Journal, *Sept. 19, 1953, page 258, the consultant who answered the query "Penicillin Reactions" said that "the addition of an antihistaminic drug to penicillin for parenteral administration will not prevent the occurrence of sensitivity reactions." This statement is contrary to the experience of many qualified workers. Some of the data disagreeing with this consultant were presented at the Scientific Exhibits of the American College of Allergy in Pittsburgh in April, 1952, and of the American Medical Association in Chicago in June, 1952. Our studies were done with chlorprophenpyridamine (Chlor-Trimeton) in a solution containing 100 mg. per cubic centimeter.*

Your consultant furthermore stated, "In some patients, not all, sensitivity to penicillin G is not accompanied by allergy to penicillin O; in these cases the latter agent can be given if there is fear of a dangerous reaction to penicillin G." Physicians treating patients sensitive to penicillin G with injections of penicillin O should proceed with extreme caution and should fear anaphylactic reactions, since it has been shown that there is a high degree of cross sensitization between penicillin G and O. (Risman, G., and Boger, W. P.: J. Allergy **21:***425-431, 1950.)*

M. Sanger, M.D.
L. Maslansky, M.D.
S. Grosberg, M.D.
M. M. Peshkin, M.D.
50 Central Park West
New York 23

To the Editor:—*In the Queries and Minor Notes* (The Journal, *Sept. 19, 1953), your consultant stated that the addition of an antihistaminic drug to parenterally administered penicillin would not prevent the occurrence of sensitivity reactions. The incidence of such reaction has been reported repeatedly to vary from 2 to 10% (Collins-Williams, C., and Vincent, J.:* Ann. Allergy **11:***454 [July-Aug.] 1953). However, with addition of an 0.2% solution of chlorprophenpyridamine (Chlor-Trimeton), Simon reports an incidence of 0.64%* (Ann. Allergy **10:***187 [March-April] 1952). Jenkins* (Ann. Allergy **11:***96 [Jan.-Feb.] 1953) reported no sensitivity reactions after 590 injections of pencillin to which 10 mg. of chlorprophenpyridamine (0.1 cc. of a 100 mg. per cubic centimeter solution) had been added. Sanger and co-workers* (Ann. Allergy **11:***354 [May-June] 1953) reported a series of 897 patients given 1,055 injections of penicillin with 10 mg. of chlorprophenpyridamine in which only one patient (0.1%) experienced mild generalized urt caria. A report is now being prepared of 1,500 cases wi only three mild reactions (all three in known penicilli sensitive patients) in patients in whom the 10 mg. dose p injection was used. Thus there would seem to be defini evidence that antihistaminics will reduce the percentage antipenicillin reactions.*

Eugene J. Luippold, M.D.
Community Medical Group
West Main St.
Boonton, N. J.

To the Editor:—*After reading the answer to the questi "Will the addition of an antihistamine to parenterally a ministered penicillin control the occurrence of sensitivi reactions due to the penicillin" that appeared in Queries a Minor Notes* (J. A. M. A. **153:***258 [Sept. 19] 1953), I belie that a documented answer with results in over 5,000 patien treated should carry more weight than one man's opinio In five of my own papers* (Ann. Allergy **8:***194, 1950;* **9:***66 1951;* **10:***187, 1952;* **11:***218, 1953; and* Arch. Dermat. Syph. **62:***314, 1950) it was shown conclusively that the r action rate with various antihistaminics added to crystalli potassium penicillin G is materially reduced from an avera of about 5% to 0.72% in 5,000 patients. When optimu amounts of the antihistaminic were added to the penicilli the figure was reduced even further, never above 0.5% a in our last 2,000 patients below 0.2%. Our results ha been substantiated by others (Jenkins, C. M.:* Ann. Aller **11:***96, 1953. Maslansky, L., and Sanger, M. D.:* Antibioti & Chemother. **2:***385, 1952. Davis, J.:* New York J. Me **53:***69, 1953) repeating our work.*

S. William Simon, M.D.
4100 W. Third St.
Dayton, Ohio

To the Editor:—*In Queries and Minor Notes under th heading "Penicillin Reactions"* (J. A. M. A. **153:***258 [Sep 19] 1953) your consultant states, "The addition of an ant histaminic drug to penicillin for parenteral administratio will not prevent the occurrence of sensitivity reactions." Th gentleman probably is unaware of the published works S. William Simon (summarized in* Ann. Allergy **11:2** *[March-April] 1953). In studies employing various ant histaminic agents injected with penicillin, Dr. Simon saw total of 34 reactions in 4,687 patients, a reaction rate 0.725%. In 1,237 patients to whom tripelennamine (Pyr benzamine, Ciba) hydrochloride was given in a mixture wit penicillin, only three reactions (0.24%) were seen. Of thes two might have been caused by a sulfonamide or anoth antibiotic. To quote Dr. Simon, "If numbers mean an thing, our experiences in over 5,000 patients given Penicilli with antihistamine added should convince the most skeptica that the rate of reaction thus obtained is far below tha resulting from the same Penicillin without the antihistamin or from other Penicillin combinations." Since reaction rate to "unfortified" penicillin of 10 to 53% have been reported these results constitute a tremendous improvement.*

NEOPLASMS OF THE SKIN

To the Editor:—*The reply to the query regarding neoplasm of the skin in* The Journal, *Oct. 24, 1953, page 776, said "The currently accepted treatment for neoplasms of th skin, exclusive of malignant melanoma, is wide local excision." This is a somewhat dogmatic statement with which numerous competent specialists will differ. Many neoplasms of the skin can be expertly treated with such measures as electrosurgery, x-irradiation, or radium radiation, with results that are excellent both therapeutically and cosmetically.*

RELATIONSHIP OF OBESITY TO CORONARY DISEASE AND HYPERTENSION

Arthur M. Master, M.D., Harry L. Jaffe, M.D.
and
Kenneth Chesky, M.D., New York

For many years, the relationship between obesity and heart disease and hypertension has presented a challenging problem. The physiological effects of obesity on the normal heart and its harmful influences on the diseased heart are well established.[1]

Statistics compiled by insurance companies have shown conclusively that overweight alone is injurious and shortens life.[2] In middle and later life the lowest mortality ratios were observed in those whose weight was below the average for age.[3] There is overwhelming evidence, also, that obese persons have a much higher mortality rate from heart disease than those of average or lower weight. The difference has been as high as 60% for men who are 25% or more overweight.[4]

There have been few clinical studies on a possible etiological relationship between obesity and coronary disease and hypertension, and the results reported have been conflicting. The problem of the relationship of obesity to heart disease and hypertension is important because both conditions are widespread. In a study of 10,000 unselected persons, 28% were found to be 10% or more above their ideal weight, according to sex and height.[5]

The relationship of obesity to hypertension requires further investigation because of the recent proposal of new standards of hypertension by Master, Dublin, and Marks.[6] They investigated the blood pressure in 74,000 persons gainfully employed in 16 industrial plants and air force fields (civilian personnel), and 16,000 of these readings were used as a sample for statistical analysis.

In our report we shall present data concerning the frequency of obesity in coronary disease and hypertension in a large series of cases. We have used the limits of normal blood pressure recently proposed.[6] We also employed, as controls, the new weight tables obtained in the large series of gainfully employed persons (table 1) by comparison with the standard weight tables established in 1912.[7] This large series is representative of the present general population. It will be noticed that, after the age of 40, women are definitely more obese than men (table 1).

MATERIAL

We investigated the frequency of obesity in essential hypertension, angina pectoris, coronary insufficiency, and coronary occlusion among unselected private patients, in all of whom the height and weight were known (table 2). They were grouped as underweight (10% or more), average weight, overweight (10 to 24% above average), and obese (25% or more above average) according to the standard weight tables established in 1912 and those employed generally. The frequency of each weight group in our cases was then compared, according to age, with similar weight classifications determined in the series mentioned above.[6] The ages of the patients in

From the Cardiographic Department, Mount Sinai Hospital.

Because of lack of space, the bibliographic references have been omitted from THE JOURNAL and will appear in the authors' reprints.

Mr. Herbert H. Marks, the Metropolitan Life Insurance Company, New York, gave statistical assistance, and Miss Iris Kanner helped collect the data.

the group serving as controls ranged between 20 and 64 years, and 90% of our patients also fell within these limits.

Obesity and Coronary Disease.—There is considerable difference of opinion concerning the relationship between obesity and coronary disease. Some authors have stated that coronary artery disease and occlusion are commoner in those who are overweight.[8] Among Army officers, cardiovascular renal disease was found to develop much more frequently in those who were overweight.[9] In Wilens' postmortem material,[10] advanced coronary artery disease was much more frequent among the obese and was found in only 6.7% of those whose nutritional status was poor. Yater and associates [11] and Gertler and co-workers,[12] however, were unable to establish an etiological relationship between obesity and coronary artery disease in young patients. Gertler and co-workers, in somatotype studies, found that coronary disease and occlusion are apt to occur in persons of mesomorphic habitus, i. e., those with well-developed musculature, rather than in the obese.

TABLE 2.—*Weight of Patients with Angina Pectoris, Coronary Insufficiency, Hypertension, and Coronary Occlusion with Relation to Standard Weight*

Disease According to Weight Group	Men, % of Total		Women, % of Total	
	Sample	Control	Sample	Control
Angina pectoris				
Underweight	12.0	30.3	29.0	29.4
Average weight	49.0	48.6	52.0	43.9
Overweight	32.0	14.8	15.0	15.1
Obese	7.0	5.3	4.0	11.5
Total cases, men	100		...	
Total cases, women	...		100	
Coronary insufficiency				
Underweight	4.4	30.3	11.5	29.4
Average weight	55.6	48.6	61.8	43.9

Average weight	43.0	48.6		
Overweight	33.0	14.8		
Obese	16.0	5.3		
Total cases, men	100			

We divided our patients with coronary disease into three groups; those with angina pectoris, acute coronary insufficiency, or acute coronary occlusion. Episodes of coronary insufficiency are severer than angina pectoris and often simulate coronary occlusion.[13] Coronary insufficiency, however, differs from coronary occlusion in cause, pathological changes, electrocardiographic findings, and treatment. Coronary insufficiency occurs when the coronary flow is inadequate to meet the demands of the heart muscle and is, therefore, induced by conditions increasing the work of the heart, reducing the coronary flow, or diminishing the oxygen content of the blood. There is no acute occlusion of a coronary artery. Focal areas of necrosis may appear in the subendocardial area. Treatment is directed against the precipitating condition, e. g., repeated transfusions are given for sudden hemorrhage. Coronary occlusion, on the other hand, occurs spontaneously, and its therapy is symptomatic.[14]

Angina Pectoris.—There were 100 men and 100 women with angina pectoris, but none had suffered a severe acute episode necessitating bed rest. There was a significant increase in the proportion of overweight men as compared with the controls, the ratio being 39 to 20 (table 2). On the other hand, the proportion of obese women with angina pectoris was even less than in the control group.

Coronary Insufficiency.—One hundred thirty-nine patients, of whom 113 were men, had experienced one or more attacks of acute coronary insufficiency, e. g., pain associated with RS-T depression and T-wave changes in the electrocardiogram that disappeared after a number of days. This type of change indicated ischemia or necrosis of the subendocardial area without acute thrombosis of a coronary artery. As in angina pectoris, the proportion of overweight men with acute coronary insufficiency was almost double that in the control group the ratio being 39 to 20% (table 2). No difference was found in the women.

Coronary Occlusion.—In taking the histories of patients with previous coronary occlusion, those with large Q-waves and RS-T elevation in their electrocardiograms, it was found that the vast majority of them had been placed on strict diets after the attack and that they had lost a great deal of weight. As a result, they showed the same frequency of obesity as did the controls; therefore, the weight prior to the attack was individually determined in 100 men. They showed a definite increase in frequency of overweight, 33 to 14.8%, and of obesity, 16 to 5.3%, as compared to the normal group (table 2). Weights were obtained in an insufficient number of women for statistical purposes.

Essential Hypertension and Obesity.—Numerous statistical studies have conclusively shown that the blood pressure, particularly the systolic, is significantly higher in normal obese persons than in those who are of average weight or underweight.[15] This has recently been shown to be true also in the rat.[16] Similarly, hypertension occurs more frequently in the obese.[17] In 1,332 healthy men, Huber [15b] found that 18% of those who were overweight had high blood pressure while almost half of those who were 10% underweight had a subnormal blood pressure. Levy and his associates [9b] noted that sustained hypertension developed in obese Army officers two and one-half times as frequently as in men not overweight. Furthermore, it has been shown that a reduction in weight is often followed by a fall in blood pressure in both normal and hypertensive persons.[18] A loss of 10 lb. (4.5 kg.) was found to cause an average drop of 15 mm. Hg in the systolic pressure and 10 mm. Hg in the diastolic pressure.[18b] Moschcowitz [18c] has suggested that in obesity hypertension is a compensatory effect to meet the increased burden on the heart, which may not keep pace in size and weight with the growth of the body. This theory would account for the drop in blood pressure after loss of weight and for the tendency of thin persons to have low blood pressure.

Among the 1,000 patients studied, there were 169 with hypertension, according to the recent criteria of Master, Dublin, and Marks.[6] One hundred eighteen were men and 51 were women. Among the men, overweight was decidedly more frequent than it was among the general population, the ratio being 32.2% to 14.8% (table 2). The percentage of distinctly obese men, those whose weight was 25% or more above the standard, however, was the same in the hypertensive and control groups, 6 to 5.3%. There was no significant difference in the frequency of obesity among the hypertensive women and the control group; the figures were 31.4 and 26.6% (table 2).

COMMENT

The literature and our own findings, in this and previous investigations, clearly indicate the importance of avoiding obesity in cardiovascular disease. In patients who are overweight, the mortality rate is twice that of average or underweight patients.[10] Obesity increases the basic work of the heart and thus places a strain on it.

It is apparent that hypertension, as defined by the new criteria, is found more commonly in obese men than in those who are of average weight or who are underweight, but the exact relationship between hypertension and obesity remains obscure. There is no definite evidence that the obesity is causally related to the hypertension. It may be that the factors resulting in hypertension also produce obesity, e. g., emotional influences, faulty metabolism, or a hormone disturbance. It is questionable that obesity is ever the sole factor in the development of hypertension, for it is quite common to find a normal blood pressure in the presence of excessive obesity. There is no doubt, however, that overweight is detrimental when the blood pressure is already elevated and that improvement usually follows a loss of weight.

Overweight is also much commoner among men who suffer from coronary disease than in the control groups.[10] This fact does not necessarily prove a causal relationship; other suggestive evidence has been presented by Gofman and Jones.[20] They found the S_f 35-100 particles in the blood were moderately related to obesity and that the S_f 12-20 particles showed a lesser, but yet significant, relation to obesity. Since these particles are increased in patients with coronary sclerosis, they concluded that obesity was related to this disease.

In cardiac disease, obesity predisposes the patient to anginal pain and congestive failure. It has been shown that obesity increases oxygen consumption, cardiac rate, blood pressure, and cardiac work. It reduces work tolerance, cardiac reserve, and vital capacity after exercise.[1] Conversely, loss of weight is usually very beneficial to obese patients with cardiac disease; their cardiac reserve is increased and their symptoms may disappear for long periods.[1] It is significant that we found a low incidence of overweight among patients who had made a long-lasting, complete functional recovery from coronary occlusion and insufficiency.[21] In these patients, the avoidance of overweight probably was a factor in the complete functional recovery from severe acute episodes of coronary disease.

A surprising finding in our cases was the failure of the women to show a greater proportion of overweight than the controls. Although this observation is being investigated in a large number of women before it is accepted, it suggests that in women, unlike men, the development of hypertension and coronary disease does not depend on obesity. The reason for this possible difference between the sexes is not obvious. We have mentioned one observation that is of possible significance, the proportion of obesity in the control group was much higher in the women than in the men.

SUMMARY AND CONCLUSIONS

The relation of obesity to heart disease is reviewed. The harmful influence of obesity on the normal and on the diseased heart is well established. Persons with heart disease or hypertension who are obese have a much higher mortality rate than those who are of average weight or below.

New standards of weight and of hypertension for the general population were employed in this investigation. These recently established limits are more representative of the present population than the figures previously employed. The frequency of obesity in patients with heart disease in private practice was ascertained. There was a definite increase in the relative frequency of overweight in men with coronary disease, including angina pectoris, coronary insufficiency, and coronary occlusion. Obesity is a strain on the heart and is capable of aggravating coronary disease. On the basis of the new criteria of hypertension, overweight occurred more frequently among men with hypertension than among the general population.

In women, obesity was not more frequent than in the normal population. This observation is being investigated in a large series of women. The reason for the possible difference between the sexes is not obvious It may be significant that the proportion of obesity in the control population is higher in women than in men. The development of coronary disease and hypertension in women may not be influenced by obesity.

Although obesity occurs more commonly in patients with hypertension or coronary disease, no definite conclusion concerning the etiological relationship between obesity and these diseases can be drawn. The reports in the literature and our own observations, however, clearly indicate the importance of avoiding obesity in cardiovascular disease.

Fifth Ave. at 100th St. (29) (Dr. Master).

Widowhood.—Where husband and wife are the same age, the chances that the wife will outlive her husband are 60 to 100, but they rise to 70 where the husband is 5 years older, and to almost 80 if he is her senior by 10 years. Widowhood is practically a certainty for wives 20 or more years younger than their husband, the chances in such extreme instances being of the order of 90 in 100. Only if the wife is at least 5 years older than her husband are the odds against her being widowed. The median age at which wives enter widowhood is about 56 years. However, a significant number are much younger when their family life is disrupted by the death of the husband; almost one-quarter of the new widows each year are under age 45. Although widowhood has been postponed to the older ages, most women still have many years of life ahead of them after their husband dies. . . . Three quarters of the women who are widowed at age 50 will live 20 years longer; that many years of life also remain for nine out of every 10 wives bereft of their mates before age 40. Even at age 65, fully one half of the widows can expect to survive for 15 years and almost one third for 20 years.—Metropolitan Life Insurance Company, Widowhood and Its Duration, *Statistical Bulletin*, September, 1953.

EVALUATION OF ADRENAL RESECTION AND SYMPATHECTOMY IN NINETY-NINE PERSONS WITH HYPERTENSION

William A. Jeffers, M.D., Harold A. Zintel, M.D., Joseph H. Hafkenschiel, M.D., A. Gorman Hills, M.D.
Alfred M. Sellers, M.D.
and
Charles C. Wolferth, M.D., Philadelphia

This study was begun in March, 1950, after a subtotal adrenalectomy was completed in a patient in whom severe hypertension had recurred one year after a thoracolumbar sympathectomy was performed. As our series of patients increased, we reported encouraging results [1] after employing various types of sympathectomy and various degrees of adrenal resection. This analysis includes 99 such patients followed for from 1 to 37 months after operation. It is our present feeling that sympathectomy combined with adrenalectomy is more effective than either sympathectomy or adrenalectomy alone. We feel, however, that further observations are required to prove or disprove this impression.

INDICATIONS AND CONTRAINDICATIONS

We have required that all three of the following indications be present before operation is attempted. 1. Average diastolic blood pressures should be 120 mm. Hg or more. 2. There should be failure to respond to intensive medical therapy. 3. There should be evidence of progressive damage to the heart, kidneys, brain, or eyes. From our experience to date, any one of the following factors is a contraindication to operation: (1) poor renal function, with excretion of less than 20% of phenolsulfonphthalein 15 minutes after intravenous injection, and/or a blood urea nitrogen of over 20 mg. per 100 cc., (2) convalescence from a stroke or coronary occlusion for less than six months, (3) age above 55 years, and (4) inability of the patient to cooperate in a careful postoperative program because of intellectual deficit or emotional instability.

TYPES OF OPERATIONS PERFORMED

The Peet sympathectomy and the modifications c the Adson and Smithwick procedures that one of ı (H. A. Z.) has performed in these patients are illustrate in figure 1. The modified Adson sympathectomy include removal of the 12th thoracic and the upper two lumba sympathetic ganglions, together with interruption of th three splanchnic nerves. The modified Smithwick sympathectomy includes removal of the lower six or seve thoracic ganglions and the three lumbar ganglions, tc gether with excision of the three splanchnic nerves abov the diaphragm. With but few exceptions, operations wei performed through a retroperitoneal incision in two stage about 10 days apart.

After observing the results of various types of adrena resection in the first 10 patients, it was found that sufficient adrenal tissue had been removed when a fragmen equivalent to a 5 or 6 mm. cube remained adjacent to th adrenal vein on the left side and when all of the righ adrenal gland had been removed. This is our meanin of subtotal adrenalectomy with respect to most of th patients who had combined subtotal adrenal resectio and sympathectomy. The various types of operation performed on the 99 patients of this series are listed i table 1.

A relatively large number of patients has been followe for not more than six months, and few have been followe for as long as 37 months. The duration of postoperativ observation at six month intervals is shown in table 2

METHOD OF EVALUATION

Our classification of the status of patients after operation included four groups—A, excellent, B, fair, C, poor, and D, failure. Group A included persons with blood pressures less than 150/100 mm. Hg both lying and standing. Group B included those with blood pressures more than 150/100 lying but less than 150/100 standing. Group C included patients in whom the blood pressure was essentially unchanged after operation. Signs and

symptoms were, however, improved in patients in this group. Group D consisted of patients in whom the blood pressure, signs, and symptoms were unchanged after operation. Careful and repeated postural blood pressure tests[2] are essential for this classification. In addition, repeated clinical examinations and special laboratory tests have been performed before and after operation.

25-30	12
31-37	6

RESULTS

Figure 2 shows the results now apparent in relation to various combinations of sympathectomy and adrenalectomy and to adrenalectomy alone. Patients who died, even though they may have shown temporary improvement, are included in this analysis only as mortalities. It is evident that we have concentrated on testing the effect of an Adson sympathectomy combined with either total or subtotal adrenalectomy. We have also classified our patients prior to operation according to the semiquantitative grading system devised by Smithwick.[3] Its usefulness is suggested (table 3) by the relatively poor results among those with the poorest prognosis (Smithwick group 4); on the other hand, it is of interest that 6 of 52 patients, initially in Smithwick group 4, have shown an excellent response up to this time.

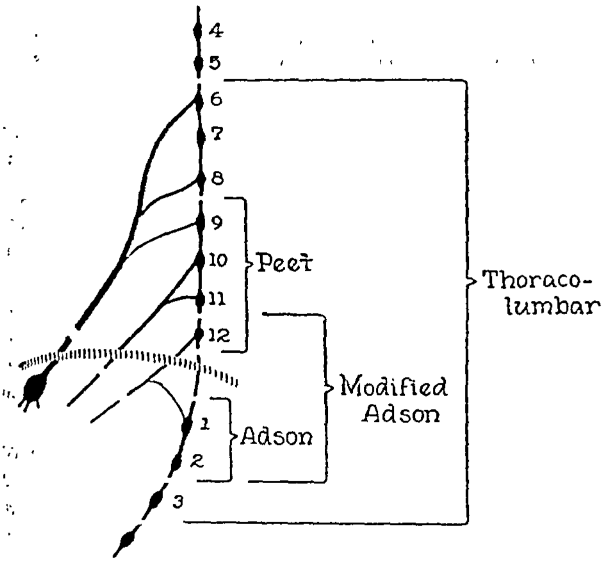

Fig. 1.—Types of sympathectomy commonly employed for the treatment of hypertension. The so-called total sympathectomy of Grimson is not included in this diagram. (Reproduced with permission from the *Annals of Internal Medicine*, August, 1953.)

Since 52, or over half, of our patients fell into Smithwick group 4, the loss of 24 of them within 37 months after operation was not unexpected. An operative mortality of only 8%, within a month after operation, seems creditable. The usual cause of death was a cerebral vascular accident or a coronary occlusion. Only one patient died from adrenal insufficiency.

Table 4 shows the percentile incidence of improvement with respect to heart size (45%), ocular fundi (45%), electrocardiographic abnormalities (41%). As improvement we included any persistent diminution in the heart's frontal area, any persistent decrease in the grade of retinopathy, and any progressive tendency for abnormalities of the QRS and T-waves to revert toward normal. Of 56 patients adequately studied, 10 showed no albuminuria and 25 no cylindruria before or after operation. In 10 albuminuria and in 6 cylindruria was present in the same degree before and after operation. In six albuminuria and in eight cylindruria was more abnormal after than before operation. In 30 albuminuria and in 17 cylindruria was less abnormal after operation than before. Of the 30 showing less albuminuria, only 7 had a change from 3 plus

to 1 plus or less. Fourteen had only a trace of albumin prior to operation, with none detected after operation. Improvement with respect to cylindruria was observed less frequently. A sufficient number of urinalyses were not available to warrant similar comparison in the remaining 43 patients. There has not been, to date, consistent evidence of improvement in renal function, as measured by repeated phenolsulfonphthalein tests or by special clearance studies.

Table 5.—*Postoperative Course of Forty Patients Who Had Paroxysmal Dyspnea and Congestive Heart Failure Before Operation*

		Postoperative				
					Dead	
	Preoperative	A	B	C	Heart Failure	Other Causes
Paroxysmal dyspnea...	19	5	5	4	0	5
Frank heart failure....	21	3	4	7	0	7

The clinical course of patients who had angina pectoris or a coronary occlusion prior to operation was also studied. All of those with only mild angina were relieved of this symptom. Patients with severer coronary disease have shown at best a variable course. Of eight patients with frequent attacks of angina preoperatively, three were relieved of angina, three survived coronary occlusions, and one died from a coronary occlusion. Five patients, in whom angina had not been present preoperatively, died from coronary occlusions after operation.

The fate of patients who showed congestive heart failure or paroxysmal dyspnea prior to operation is shown in table 5. It became apparent early in our study [4] that a tendency toward heart failure was apt to be corrected after this operation, and this has continued to be a striking phenomenon.

It appears proper to continue to operate on patients who have had a good recovery from cerebral vascular accidents for at least six months. Table 6 indicates the course of patients with evident cerebral vascular damage.

REPLACEMENT THERAPY

Our observations to date indicate that a favorable response to adrenal resection, either alone or combined with sympathectomy, is infrequent unless sufficient adrenal tissue has been removed to render the patient susceptible to adrenal insufficiency when cortical replacement therapy and salt are withdrawn. Hills and co-workers [5] have made a quantitative estimation of residual adrenal function in 10 patients after operation. They used a method developed for the purpose.

Table 6.—*Postoperative Course of Nineteen Patients Who Had Preoperative Cerebral Vascular Damage*

		Postoperative					
						Dead	
	Preoperative	A	B	C	D	Stroke	Other Causes
Without residuals..............	9	2	4	1	1	1	0
With residuals...................	10	1	1	4	0	3	1

Table 7 gives a schedule of the amounts of cortisone, desoxycorticosterone (DCA), and sodium chloride used in connection with operation. During the first month after operations that include extensive adrenal resection, a liberal amount of cortical replacement therapy has been given, if blood pressures are not higher than 180/100 mm. Hg or there is the usual marked fall in blood pressure on standing. This may include cortisone, 37.5 to 50 mg. in divided dosage daily, desoxycorticosterone, 2 mg. buccally, and enteric-coated tablets of sodium chloride, 3 to 6 gm. daily. Later, the dosage of cortisone, salt, and desoxycorticosterone is diminished in each patient to achieve an optimal level of blood pressure, while avoiding anorexia, nausea, or hyperkalemia. With the onset of warm weather, an increase in the amount of replacement therapy is necessary. Patients are instructed to report anorexia or nausea promptly to their physicians and to seek medical care without delay in the event of a respiratory infection or other febrile episode, in order that replacement therapy can be increased temporarily.

Table 7.—*Schedule of Replacement Therapy Used in Connection with Second Operation of Total or Subtotal Adrenalectomy*

	Cortisone	Desoxycorticosterone (DCA)	Other
Day of operation	50 mg. intramuscularly just before operation; repeat 6 hr. after operation	0	2,000 cc. 5% dextrose in water slowly, 1,000 cc. 5% dextrose in sodium chloride solution slowly, or 1,000 cc. blood
First postoperative day	50 mg. intramuscularly every 12 hr.	0	As above
Second and third postoperative day	25 mg. orally every 8 hr.	2 mg. buccally	1-2 gm. orally after each meal
Fourth postoperative day	25 mg. orally every 12 hr.	As above	As above

COMMENT

The operative approach for the treatment of severe hypertension that we have chosen to follow is an attempt to combine the possible benefits of sympathectomy of the Adson or Smithwick type with subtotal or total adrenalectomy. The Adson sympathectomy, combined with adrenal resection and performed in two separate stages, has been well tolerated by most patients who have had adequate preservation of renal function. Their convalescence has been marked by its ease and freedom from the pulmonary complications and prolonged backaches that may follow thoracolumbar sympathectomy. It will require further observation to establish whether, or under what circumstances, this type of operation will prove superior in the long run to (1) thoracolumbar sympathectomy, (2) thoracolumbar sympathectomy plus subtotal or total adrenalectomy, or (3) total adrenalectomy alone.[6]

Operations of this sort cannot be attempted without a well-integrated medical and surgical team that is prepared to deal not only with all surgical complications but with any of the manifestations of severe hypertensive cardiovascular disease or adrenal insufficiency. In the case of each patient, a prolonged and careful follow-up is obligatory. A member of the team must be on call at all times, and he must be prepared to treat acute adrenal insufficiency or any other emergency. We have encountered to date no greater difficulty in managing patients after total adrenalectomy than after subtotal adrenalectomy. Our patients do not appear to lack energy and vigor for their full work loads unless they have cardiovascular complications. The only symptom frequently mentioned is a mild intolerance to cold.

SUMMARY AND CONCLUSIONS

The results of various degrees of adrenal resection with and without various types of sympathectomy in 99 patients with severe hypertension are reported. To be eligible for operation patients fulfilled all of the following qualifications. They had (*a*) an average diastolic blood pressure of 120 mm. Hg or more, (*b*) lack of response to intensive medical therapy, and (*c*) evidences of progressive vascular damage. Tentative contraindications include any one of the following factors: (*a*) poor renal function, (*b*) less than six months' convalescence from a stroke or coronary occlusion, (*c*) age over 55 years, or (*d*) inability, for any reason, to cooperate in taking adrenal cortical replacement therapy.

The majority (70) of patients were subjected to an Adson sympathectomy, plus either subtotal or total adrenalectomy. In the case of subtotal adrenalectomy, all adrenal tissue was removed except a piece about 6 mm. in diameter adjacent to the adrenal vein on the left side. Operations were performed through a retroperitoneal incision and in two stages about 10 days apart. Further observation must be made to determine whether the Adson sympathectomy, combined with total or subtotal adrenalectomy, is more or less effective than thoracolumbar sympathectomy or total adrenalectomy without sympathectomy.

During the period of postoperative observation of the 99 patients, 23% showed an excellent response, 23% a fair response, and 30% a poor response; 24% died. Only one patient died from uncomplicated adrenal insufficiency; the usual cause of death was a stroke or a coronary occlusion. Patients with paroxysmal dyspnea or congestive heart failure prior to operation showed the most striking improvement. This appears to be primarily the result of extensive resections of adrenal cortex. Most of those subjected to subtotal adrenalectomy required adrenal cortical replacement therapy after operation. Objective changes have been observed in the heart size, retinopathy, and electrocardiographic findings. Precautions necessary for the successful management of patients subjected to these procedures are discussed.

PROBLEM OF THE GASTRIC ULCER REVIEWED

STUDY OF ONE THOUSAND CASES

Frances H. Smith, M.D., Russell S. Boles Jr., M.D.
and
Sara M. Jordan, M.D., Boston

The problem of gastric ulcer continues to be a subject of controversy because of the association of this disease with cancer of the stomach. Since surgeons and gastroenterologists are so often confronted with the grim and frustrating circumstances that surround the diagnosis and treatment of gastric cancer, it is natural that any lesion of the stomach should be considered potentially malignant. Such fear is indeed justified if it breeds a vigilance that may result in the early detection of cancer; however, it must not be forgotten that benign ulcers of the stomach with potentiality of complete healing do occur.

Ulcerating lesions of the stomach fall into one of two categories: (1) ulceration in an infiltrating lesion, grossly recognized as malignant, and (2) ulceration with an appearance of peptic ulcer. The disposition of the first group is, of course, to immediate surgery, with the hope that operation is possible and the condition is still without metastatic involvement. In the second group, the peptic ulcer that may be benign can be finally diagnosed as such only when histological examination or adequate clinical evidence of healing furnishes proof of this diagnosis. And it is over this point that there is controversy. Some physicians believe that excision of the lesion and histological examination are the only proof of diagnosis and the only guarantee of safety, while others believe that intensive treatment under observation and inspection of healing is adequate proof that the lesion is a benign ulcer, which, when healed, carries no potential danger of malignancy.

CASE MATERIAL

This study deals with 1,000 patients who had gastric lesions of this second group that, when first seen, could reasonably be regarded as benign ulcers. It is our intention to indicate by statistics the fate of these 1,000 patients. Most of the cases previously reported [1] by two of us (1948) are included. In the present study, 578 patients were operated on and 422 had medical treatment alone. There were 912 (91.2%) patients with benign gastric ulcer and 88 (8.8%) with malignant ulcer. In the group of 912 patients, 635 (70%) were male and 277 (30%) were female. Of the 88 patients with malignant ulcer, 64 (73%) were male and 24 (27%), female.

The ages of the patients included in this study ranged from 10 to 89 years. Their distribution followed the expected pattern since the ages of the largest number of patients with benign and malignant ulcers, both surgically and medically treated, fell in the sixth decade. In the

[1] Smith, F. H., and Jordan, S. M.: Gastric Ulcer: Study of 600 Cases, Gastroenterology 11:575-597 (Nov.) 1948.

surgically treated group, the ages of five patients with benign ulcers and four with malignant ulcers were in the third decade. In this group, there was one patient with benign ulcer whose age was in the ninth decade. Among the patients who had medical treatment only, the ages of three with benign ulcers were in the second decade and of six in the ninth decade.

Gastric resection was performed in 474 patients with benign gastric ulcer, and in 7 of these all of the stomach was removed. Gastric resection was performed on 60 patients with malignant ulcers, and nine total gastrectomies were performed in this group. In 23 patients with benign ulcers and 21 patients with malignant ulcers, other surgical procedures, including exploratory laparotomy, repair of perforation, gastroenterostomy, and ligation of a bleeding artery, were used. There were 415 patients with benign gastric ulcers and 7 patients with malignant gastric ulcers who had medical treatment only. Of 578 patients who had surgical intervention, 541 were operated on within five years after their first admission, and of this group 512 had gastric resection. Thirty-seven patients, of whom 22 had resections, were operated on later than five years after their first admission. Two hundred twenty-four patients were treated medically and followed for five years or less, and 198 patients were treated medically and followed for more than five years.

Table 1.—*X-ray Location of Gastric Ulcer in 963 Patients*

	Benign		Malignant	
	No.	%	No.	%
Fundus	45	5.2	5	6.0
Media	518	58.9	47	55.9
Antrum	96	10.9	13	15.5
Prepylorus	157	17.8	14	16.6
Pylorus	63	7.2	5	6.0
Total	879	100	84	100

It is striking in this study that there was no significant difference in the weight loss in the groups with benign and malignant ulcer; 35% of the patients with malignant ulcer and 37% with benign had lost no weight. Approximately 42% of the patients with benign or malignant ulcer lost 11 lb. (5 kg.) or more, and marked loss of weight (20 lb. [9.1 kg.] or more) was found in about 19% in both groups. The deduction from these statistics was, therefore, that although loss of weight occurred with malignant gastric ulcer in 65% of the patients it was of questionable significance as a point of differentiation between a benign and a malignant ulcer since it also occurred with benign ulcer in 62% of the patients.

GASTRIC ANALYSIS

Since histamine stimulation was not used in most of the 867 patients who had gastric analysis, the results may be considered to represent functional secretion. In the group with malignant ulcer, the percentage of patients with achlorhydria (8.8%) was only 3% less than that of patients with hyperchlorhydria (11.8%), and the largest percentage (57.3%) was in the normal range of acidity. In the group with benign ulcer, the largest number of patients was in the normal range, but 5.1% had lorhydria.

X-RAY EXAMINATION AND GASTROSCOPY

Although malignant ulcers are found to occur anywhere in the stomach, ulcers in certain areas, notably the prepylorus and the greater curvature, are generally considered to have a much greater incidence of malignancy. In our present study, 22.6% of benign ulcers and 28.1% of malignant ulcers were located in the prepylorus on pathological examination. These figures differ from those that would have been derived from roentgenologic study alone, as the following discussion shows.

In 37 patients of the series of 1,000 cases the diagnosis of gastric ulcer was not proved or reported preoperatively, chiefly because operation was done for acute abdominal conditions or obstruction. Of the 963 patients who had x-ray examination, 515 (451 with benign ulcer and 64 with malignant) were operatod on and the actual location was reported by the pathologist (table 1). Roentgenograms showed that the benign ulcers of 97 patients were in the prepylorus and of 44 patients were in the pylorus. Of the 97 prepyloric lesions, 11 were found by the pathologist to be pyloric, which made 86 prepyloric and 55 pyloric lesions. Of the 44 ulcers reported to be in the pylorus by roentgenograms (actually 55), 16 were found by the pathologist to be prepyloric, which left 39 pyloric lesions and 102 prepyloric lesions.

Since the lesions in 451 patients who had resection performed were benign and 102 of these were proved by the pathologist to be prepyloric, the percentage of proved benign prepyloric ulcers was 22.6. In the group with malignant ulcer, 14 patients had lesions diagnosed by x-ray examination as prepyloric but one lesion was actually pyloric. Five lesions were called pyloric but were demonstrated to be prepyloric, so that in 18 (28.1%) of the 64 patients with malignant ulcer the lesion was actually prepyloric. Seventeen of the 451 benign gastric lesions that were resected were shown in roentgenograms to be on the greater curvature, but only 4 were thus described by the pathologist. It is interesting to note that the percentage of benign lesions of the media was 48 and the percentage of the malignant lesions in that area was 52. Eight of 64 malignant lesions operated on were shown in roentgenograms to be on the greater curvature. These were confirmed in the pathological examination.

By means of roentgenograms coexistent duodenal deformities were reported in 19.7% (173 of 879 patients) with benign gastric ulcer and in 20.2% (17 of 84) with malignant ulcer. These findings suggested that the demonstration of a duodenal deformity by means of roentgenograms was of no help preoperatively in differentiating a benign from a malignant ulcer. Hourglass deformity was present in 4.3% (38 of 879 patients) with benign gastric ulcer and 7.1% (6 of 84 patients) with malignant ulcer, a ratio of 6.33 to 1. Although the percentage difference between malignant and benign hourglass deformity was considerable, the total number (44) in both groups was too small for accurate deduction. In the group of patients with benign gastric ulcer, 2.4% (21 of 879 patients) had multiple ulcers. Twenty of these patients had resection and pathological diagnosis and/or surgical confirmation. In one patient the diagnosis was made with roentgenograms alone. Of the group with malignant ulcer, 1.2% (1 of 84 patients) had more than one gastric ulcer as diagnosed with roentgenograms alone.

In 5.2% of the 1,000 patients studied, gastroscopy was performed. This report includes only those cases in which x-ray visualization and symptoms were highly suggestive of malignancy and in which gastroscopic visualization of the lesion was possible. The gastroscopic diagnosis was verified by pathological examination in 20 patients with benign ulcer and 13 with malignant ulcer. The pathological findings were at variance with the gastroscopic diagnosis in 5 of the benign and 14 of the malignant ulcers.

TABLE 2.—*Reasons for Operation on 578 Patients with Gastric Ulcer*

	Benign		Malignant	
	No.	%	No.	%
Suspected malignancy	201	40.4	43	53.1
Intractability *	103	20.7	15	18.5
Recurrence	81	16.3	15	18.5
Acute hemorrhage	39	7.8	2	2.5
Multiple hemorrhages	14	2.8	1	1.2
Obstruction	50	10.1	4	4.9
Perforation	9	1.8	1	1.2
Total	497		81	

* By intractability is meant persistence of symptoms and x-ray evidence.

RESULTS IN PATIENTS WITH BENIGN ULCER

Although suspected malignancy, recurrence, and intractability were separately listed as indications for operation, in actual fact these categories might overlap, since malignancy was usually suspected when an ulcer was intractable or recurrent. Suspected malignancy was the stated reason for operation in 40.4% of the patients with benign resected ulcer and in 53.1% with malignant ulcer. Recurrence was considered an indication for resection, and table 2 shows that, of the 497 patients who were operated on for benign ulcer, 16.3% had recurrent benign lesions and, of 81 patients with malignant ulcer, 18.5% had recurrent lesions. Perforation, hemorrhage, and obstruction were of higher incidence in the group with benign ulcer than in the group with malignant ulcer.

The clinical evaluation of results as shown in tables 3 and 4 was based on the presence or absence of the following criteria: (1) distress; (2) nausea and vomiting; (3) recurrent ulcer as shown in roentgenogram; (4) hemorrhage; (5) weakness and inability to work and in the surgical group dumping syndrome and persistent diarrhea. The reports were based on clinical records and replies to questionnaires and show results that indicate little difference of morbidity in the surgically and medically treated groups.

RESULTS IN PATIENTS WITH MALIGNANT ULCER

There were 88 patients with malignant ulcer in this study. Sixty had resection; 21 who could not have resection underwent other surgical procedures, such as gastroenterostomy, suture of perforation, ligation of an artery, or exploratory laparotomy. In 30 patients the operation was performed within a week after the time the patient was first seen; 21 patients were operated on within a month; 8 patients were operated on from one to two months after their first admission, 6 of these in the years between 1935 and 1945 and 2 in 1951. Four patients had operations within two to four months, three between the years 1938 and 1945, and one in 1949. Five patients were operated on between four months and one year after their first admission, four between the years 1931 and 1944, and one in 1951. Ten patients were not operated on until one to five years after their first admission, nine between the years 1934 and 1946 and one in 1948. Three patients seen between the years 1931 and 1943 were not operated on until five years after their first admission. After 1946, only five patients were treated longer than one month before resection, although in the preceding years 25 patients were maintained beyond one month with medical treatment. Among all the patients maintained beyond one month with medical treatment, 15 had recurrences at intervals of six months to seven years after admission and 5 between one and two years after admission.

Seven patients who were not operated on died with malignant ulcer. The first patient was originally seen in 1924, and a diagnosis of benign ulcer was made. It healed completely under medical management. The patient had no recurrence for 22 years, but at autopsy, 23 years later, carcinoma in situ was found. The second patient, first seen in 1938, could not be treated surgically because of concomitant disease. He died in 1941. The third patient was first seen in 1940; surgery was advised but refused. He died in 1941. The fourth patient was originally seen in 1940 and was followed for nine months at frequent intervals, with clinical and x-ray evidence of complete healing. At autopsy six and a half years later, carcinoma of the stomach was found. The fifth patient was first seen in 1942 and could not have surgical treatment because of concomitant disease. He had apparent healing of his gastric ulcer during medical management, but at his death in 1945 a clinical diagnosis was made of malignant gastric lesion; autopsy was not performed. The sixth patient, first seen in 1943 and managed with ambulatory treatment with complete healing, was reported by his referring physician to have died four years later from a gastric lesion that was suspected of being malignant. No autopsy was performed. The seventh patient, first seen in 1945, refused operation and died in 1952.

Total or per cent	298	75.1	55	13.8	44	11.1	397

RECURRENCES AND MORTALITY

One hundred forty patients had recurrent gastric ulcer; 96 were operated on and 44 were not. In the group that underwent operation 81 had benign lesions and 15 had malignant lesions. Of the 81 patients whose benign lesions were proved pathologically, 10 had more than one recurrence. Three of the group with malignant lesion had more than one recurrence. Of the 44 patients who had recurrence and were not operated on, 41, because of x-ray and clinical evidence of healing, were considered to have had benign gastric ulcers; 7 of these patients had multiple recurrences. Three of the group without operation had malignant ulcers, and one of them had had more than one recurrence. Recurrence was usually considered a definite indication for surgery, and our findings confirmed the validity of this policy, since malignancy was found in 16% of the recurrent ulcers that were operated on, an incidence that is appreciably higher than the over-all incidence of malignant ulcers in the total series (8.8%).

Deaths in the Postoperative Period.—There were 497 patients who had a surgical and/or pathological diagnosis of benign gastric ulcer. Twenty-three (4.85%) of the 474 patients, who had gastric resection, died in the postoperative period. There were 6 postoperative deaths among the 23 patients who had surgical procedures related to their benign gastric lesions. Eleven of the total number of 29 deaths occurred before 1944; of these, 4 were from pulmonary embolism and 7 were in patients over 65 years of age. Eighty-one patients had a surgical ⑪ and/or pathological diagnosis of malignant ulcer. Sixty of these had resection, and two died postoperatively. Twenty-one patients had other surgical procedures and six of these died postoperatively.

Deaths After the Postoperative Period.—Sixty-four patients who were operated on died. Of the 44 patients with benign gastric ulcer in the group, 3 died, cause unknown, after being followed for three, four, and five years, respectively. One patient died of carcinoma of the stomach (proved pathologically) five years after resection for benign ulcer (proved pathologically). Ten died from malignant growths other than gastric cancer. In this group, there were three with carcinoma of the pancreas and one with carcinoma of the rectum. Thirty patients died of known causes unrelated to the stomach: 10 died in less than five years, 3 were followed five years, and 17 were followed more than five years after resection. Of the 20 patients with malignant ulcer, 18 died of carcinoma of the stomach and 2 died of pulmonary embolism after other surgical procedures; one of these died after a resection for jejunal ulcer. Of this group 2 were followed for 6 years, one for 6½ years and one for 11 years before death.

Deaths in the Medically Treated Patients.—Seventy-one patients with gastric lesions originally diagnosed as benign died. In five the cause is unknown. Seven (1.7%) died of carcinoma of the stomach; four of these were treated less than five years and three more than five years. Three patients died from malignant lesion in the digestive tract: one from carcinoma of the liver, the second from carcinoma of the colon, and the third from carcinoma of the esophagus. No evidence of malignant gastric lesion was found in these patients. Eight patients died of carcinoma not related to the digestive tract. Forty-eight patients were known to have died of nonmalignant disease. Eighteen of these 71 patients were followed more than 11 years; 10 were followed from 5 to 10 years.

These statistics indicate that the mortality from cancer of the stomach occurring in the unoperated cases was 1.7% whereas the operative mortality in resected cases for benign ulcer was 4.85%. There were 29 patients (2.9%) in whom death, which was attributable to carcinoma of the stomach, possibly could have been avoided by immediate operation. Of this group, 7 patients had no surgery and 22 were operated on after two months of medical treatment.

If all five patients in the group that did not undergo surgery who died of causes unknown are assumed to have died of cancer of the stomach, although this is hardly probable, this addition brings the percentage up to 3.4, which is still lower than the over-all surgical mortality in benign ulcer (4.85%). It is recognized that surgical mortality has declined in recent years, and that gastric resection has become progressively safer in all age groups. It is, however, also shown in this study that the majority of errors in clinical judgment in medical management occurred chiefly in the same years when surgical risk was high and that medical treatment for differentiation of benign and malignant ulcers has made what might be considered parallel progress with surgery.

SUMMARY AND CONCLUSIONS

One thousand cases of gastric ulcer are presented, 912 benign and 88 malignant. Four hundred ninety-seven patients of the group with benign ulcer were operated on; suspected malignancy was the indication for operation in more than half of these patients. Seven of the group with malignant ulcer were not operated on; in four of these, operation could not be performed in any case. One hundred ninety-five patients with benign ulcer who did not undergo surgery were followed for more than 5 years and, of these, 99 for more than 10 years. Seventy-three per cent of this latter group were without gastric symptoms, and a comparison of the morbidity statistics shows little difference between the results in the groups undergoing operation and those who did not.

It seems reasonable, therefore, to conclude that a month or less of intensive medical management in many cases of gastric ulcer is justified. The responsibility for differentiation is great and requires the utmost vigilance, but it seems to us that the responsibility should be borne by the gastroenterologists in the interest of avoiding unnecessary surgery and of maintaining unimpaired digestive physiology.

605 Commonwealth Ave. (15) (Dr. Smith).

Bone Bank.—Preserving bone in a penicillin-streptomycin solution is simple, requires no special equipment or trained personnel, and is inexpensive. One hundred grafts have been done using bone so preserved. There have been no infections. All bone preserved by this method and used as a graft has integrated.—Lieut. Col. R. W. Augustine and others, Penicillin-Streptomycin Bone Bank, *U. S. Armed Forces Medical Journal*, November, 1953.

ROLE OF THE DERMATOLOGIST IN THERAPY OF CANCER OF THE SKIN

CHAIRMAN'S ADDRESS

John H. Lamb, M.D., Oklahoma City

My interest in carcinoma of the skin stems from a paper I read before the Section on Dermatology and Syphilology in 1938 on radiation treatment of cancer of the lip. Since that time much of my professional work has been devoted to improvement of radiation techniques and study of cancer of the skin in the literature and in seminars. When I began this career of active scientific study three years after entering dermatological practice, I inherited from my predecessors knowledge of the then standardized physical agents, radium and x-radiation.

I did not have to combat the doubters who stated that these agents had no scientific value, that they were dangerous implements that no one could control, and that sufficient dosage to cure a cancer would also destroy the normal tissues. Neither did I have to spend time educating the public that cautery, surgery, and zinc chloride pastes had been replaced by more effective and simpler agents that produced better cosmetic effects and cure in a high percentage of cases. I could devote my time to better treatment with variations of infiltration and kilovoltage of x-rays to such locations as the ear, alae of the nose, nasocheek folds, scalp, tongue, and buccal surfaces, where lesions had been heretofore incurable with this therapy. I could learn the tolerance doses of the normal tissues in these locations, and, finally, I also had time for pathological study of many varieties of skin neoplasms. My predecessors had so established their group as "dermatologists who were cancer specialists" that no limit was put on the tools used to cure the cancer.

The kilovoltage of x-rays available ranged from 60 to 200 kv., the half-value layer from 0.9 mm. Al to 0.5 mm. Cu, with a radium emanation reservoir of 200 mg. for external radiation and over 100 mg. in low-intensity radium element needles. This heritage was a great stimulus to a then young man who was entering an era in his specialty in which many factors seemed to be narrowing and limiting the dermatological field of practice even in cancer therapy. It is apparent, therefore, that one cannot discuss the role of the dermatologist as a cancer specialist without a historical consideration of those who established our role today and how they left us this great heritage.

HISTORICAL ROLE OF DERMATOLOGISTS AS CANCER SPECIALISTS

The dermatologists were the first to study experimentally the recovery of normal tissues from radiation. Kingery,[1] a dermatologist, was the first to publish the theory that irradiation produced some hypothetical decomposition product in the tissues. Recovery from radiation effect would be in direct ratio to elimination of this product, which, he assumed, would be subject to the same law as certain other chemical and biological reactions and follow a logarithmic curve. He pioneered in a field that brought to the forefront the importance of the three factors in computation of dosages, namely, the quantity of radiation, the space or amount of tissue treated, and the factor of time. These principles have given us protraction of radiation technique and knowledge of tissue recovery, all based on these excellent early experiments of Kingery, followed by other physicists and radiotherapists such as Duffy, Arneson, and Voke,[2] MacComb and Quimby,[3] and MacKee, Cipollaro, and Montgomery.[4]

At the second annual Pusey dinner, Dr. Leonard Weber[5] reviewed the early days of our greatest pioneer in roentgen therapy, Dr. William Allen Pusey.[6] In 1899, four years after Dr. William Conrad Roentgen discovered the new ray, Dr. Pusey went to Vienna to study the x-ray techniques of Drs. Leopold Freund[7] and Eduard Schiff, who were pupils of Roentgen's. Dr. Freund not only had given the x-rays therapeutic trial but had designed proper apparatus and offered a careful technique for its safe employment. Dr. Pusey returned to Chicago inspired with the possibilities of this new agent after his visit with Dr. Freund. On an old manila envelope he listed a generalization of the indications for the therapeutic use of x-rays, then enlarged upon these indications. With a few exceptions they still stand today.

Dr. Pusey started with a crude, gas-filled roentgen tube and mechanized rectifier and attempted to apply these principles to treatment of malignant lesions. He treated many malignant lesions of the skin, both superficial and deep, on the eyelids, the lower lip, etc., with great success. He also treated the hopeless and less favorable tumors and metastases for his surgeon friends. Palliative results in recurrent carcinoma of the breast were surprising.

Dr. Pusey was the first to advocate routine prophylactic irradiation postoperatively in cancer of the breast. He reported his results with filtered x-ray therapy on leukemia with roentgen irradiation of the spleen and its

immediate effect on diminishing the number of white cells in the circulatory blood. He became interested in the therapeutic use of this new agent for skin diseases and presented a case of pseudoleukemia or Hodgkin's disease at the Chicago Medical Society on Feb. 26, 1902. Erythema was produced, and the affected glands diminished rapidly in size. As early as 1902 he published many valuable papers on the use of x-rays in the cure of cancer, and continued to produce equally important papers throughout his active life. Dr. Pusey also edited a treatise on "The Practical Application of Roentgen Rays in Therapeutics and Diagnosis,"[6e] which had many editions. Dermatologists owe a great debt to this great teacher for his early vision in the use of this agent in our specialty.

One of Dr. Pusey's early pupils was a young Oklahoma country practitioner, Dr. Everett S. Lain, who in 1908 gave up a successful general practice,[8] and went to study with Dr. Pusey. Dr. Lain returned to Oklahoma and carried out the teachings of Pusey. He gave many hours of his time to the establishment of cancer clinics over the state of Oklahoma. He became the Oklahoma representative of the American Cancer Society in this area. Thus, all of the experience of Pusey and Lain was accumulated, digested, and improved upon, then passed on to us. Our present day methods rest upon these foundations. Similar dissemination of this knowledge in the therapeutics of cancer has taken place all over this country. In some areas the seeds have fallen on fallow ground, in others on fertile soil.

DERMATOLOGICAL TRAINING FOR CANCER SPECIALIST

Since the commonest form of cancer in the male, and the third most frequent in the female, is cancer of the skin, the majority of the cases are first seen by the dermatologist. The training of a dermatologist teaches him first to be accurate in direct inspection of all skin changes. He is trained to know all forms of precanceroses and their transition to malignant lesions. Ninety-five per cent of all malignant skin diseases can be diagnosed by clinical evaluation by most dermatologists.

Dermatologists are trained to differentiate nevi clinically and microscopically, an exceedingly difficult differential to many others. They are also trained to diagnose other skin conditions which in the early stages resemble precancerous keratoses. Lupus erythematosus offers such a problem on the face. Several cases have been seen in which heavy radiation was applied to small, single lesions of lupus erythematosus, which later spread in annular, discoid plaques typical of this disease.

The dermatologist is the logical cancer specialist because of his training as a therapist. In treating the benign lesions of the skin, he learns a great deal about the tolerance of the skin for radiation. Various degrees of radiation reactions are easily discernible, and he has a "feel" of depth perception to determine the extent of the lesion and many other minor but important factors in dealing with malignant disease of the skin.

SOME ESSENTIALS FOR THE CANCER SPECIALIST

The dermatologist cannot expect a superior reputation among both patients and physicians unless he follows some definite principles to become a cancer specialist. First, his approach, therapy, and results must satisfy tl patients. In our practice, x-ray and radium therapy the method of choice, since patients are pleased with tl more effective modern radium and x-ray therapeut methods for the following reasons: 1. They are simp 2. There are no fears of "cutting on a cancer." Patier have a definite fear resulting from a lay idea that "cuttin spreads the lesion. 3. Cosmetic results are excelle Later atrophic sequelae are avoidable with filtration x-ray therapy and with the gamma rays of radium. T skin erythema dose is much higher for gamma rays radium (1,000 r) and heavier filtered x-rays (400 500 r). Thus a much higher total dosage can be giv with a lower number of skin erythemas.

Another factor of importance is cooperation and hc esty with general practitioners. Interest in palliation th apy and in all hopeless cancer conditions must be ma tained.

Also essential is cooperation with surgical staffs w are themselves cooperative and appreciate the true val of radiation techniques. Domination of cancer clin over the country by noncooperative surgeons who a opposed to radiation treatment militates against effecti utilization of these physical methods and their bene to the patient, with regard to both curative and palliati effects. The progress made in the field of cancer surge however, is truly as remarkable as that made in rad therapy.

X-ray equipment should be adequate. There is finer investment than x-ray equipment that will wi stand heavy usage. All ranges of kilovoltage should included, from a low of 60 kv. to at least 140 kv.

It is also important to buy or rent adequate radiu i. e., three 5 mg. half-strength plaques, three 10 mg. ha strength plaques, four 5 mg. radium needles in platinu ten 1.5 mg. (2 cm. length) interstitial radium elemen low-intensity needles, six 2 mg. interstitial radium e ments, low-intensity needles, and eight long 2 mg. i terstitial radium element needles 44 mm. in length. T dermatologist should be equipped to aid in treatment patients for whom his treatment has failed, i. e., the with metastatic lesions, with heavier filtration and high kilovoltage or low-intensity, interstitial radium eleme needles.

Whenever cancer is suspected, it is imperative th physical examinations by the dermatologist be comple with special attention to the vaginal orifice, oral cavi breasts, and genitalia. The method of treatment must rational and adequate and chosen most carefully. A fr quently justifiable criticism of many radiotherapists wl treat cancer is that the majority "underdose" with radi tion, then follow-up with electrodesiccation or electr surgery to produce the cure. In 1935 this was certain true in our office; two patients daily were treated with a other round of filtered x-ray therapy, cautery, or electr surgery. Today, with proper dosage, we are approachin a 100% cure rate with the first treatment.

No one method is entirely adequate—all metho must be available and understood by the dermatologis Each malignant lesion must be studied carefully as t (1) location of lesions, as normal tissues in various lo cations react differently to radiation; (2) depth; and (3 extent. With the excellent progress of cancer educatio throughout this country, the large, infected epitheliomas of the old days are gone; however, one or two such lesions are still seen weekly. These are the real test for the various methods of therapy, since most methods will handle the small, early epitheliomas.

---

[8] Lain, S.: Pioneering in the Use of X-Rays and Radium in Oklahoma, published monograph, 1952.

Microscopic study of the tumors must be a part of the dermatologist's work as a cancer specialist. It is recommended that more dermatologists become adept in the study of histopathology of the skin in order that they may study their own cancer tissues. It is encouraging to see the interest on the part of dermatologists in pathology over the past 10 years. However, I do not believe in the great importance that is being placed on the positive biopsy report; the examination, palpation, and history are of equal importance. The clinical diagnosis is based on such factors as (*a*) the history of growth of the lesion from a precancerosis; (*b*) a pearly consistency; (*c*) the presence of telangiectatic vessels over the surface; and (*d*) the presence of other precanceroses.

The sin of treating clinically malignant lesions that have been reported as microscopically benign with heavy radiation is far less than that of underestimating the same growth because of several pathological reports of nonmalignancy. This is particularly applicable when the lip and buccal cavity areas are involved. The pathological report of many biopsy specimens removed from clinically positive lesions in the buccal mucosa will be leukoplakia or leukokeratosis, nonmalignant. Nevertheless, by observation and experience it can be seen that they are already malignant and should be treated as cancer.

The biopsy has been established by many therapists as a guide for determining the dosage for each type of cancer. Our dosage is approximately the same for all types of skin cancer—be it basal or squamous. We have a very high regard for any type of skin cancer. Microscopic analysis from one tiny segment of a lesion has never given us a feeling of safety in the basal types. In the past 20 years we have had more trouble with under-radiated and, finally, radioresistant, infiltrative types of basal cell lesions than with squamous cell cancers, which everyone is taught to respect.

The biopsy presents another pitfall in the hands of the general surgeon or general practitioner who takes a small biopsy specimen in a clinically positive case and, on receiving a negative pathological report, delays radical treatment for several months while the typical cancer develops. If the lesions are borderline clinically, a biopsy specimen should be removed and therapy postponed until the tissue is studied.

For the young cancer specialist, the biopsy should be a routine procedure on each cancer patient to protect him, but as the clinical judgment becomes more accurate it need not be made routine but left to the judgment of the therapist. Many of our patients have over 10 cancers. The expense of the biopsies in such instances would preclude any further treatment of the cancers. In certain locations the removal of a biopsy may spoil the cosmetic results and, by subsequent infection, interfere with the radiation effects in such locations as the upper and lower eyelids. I plead that, if a biopsy is performed, minute slices or a scissor-bite portion of the active growth is all that is necessary.

Surgery is reserved in our practice for infiltrating basal cell carcinomas that have been improperly irradiated and are radioresistant; it is also used where the skin about the tumor will not heal when the cancer is destroyed by desiccation and curettage. Surgery is the preferred treatment for melanomas and cancers larger than 1.5 to 2 cm. on the dorsal surface of the hands and fingers. Many cancer therapists (Martin [9]) advocate electrosurgical removal of large, fungating portions of the growths before radiation is instituted. However, with proper use of varying kilovoltage and filtration, these large masses melt away and no electrosurgery is at all necessary, as it is only more painful and shock-producing to the patient, upsets the cancer bed, and disrupts the exact totaling of dosage. Any trauma may increase radiation effects. To destroy these large, fungating surface masses, unfiltered x-rays of from 1,500 to 2,000 r units in two divided doses, 100 kv., a half-value layer of 0.9 mm. Al are added to the usual heavier filtered x-ray and gamma radiation therapy. The cancer mass is closely windowed, protecting the normal skin. This radiation acts almost as an escharotic to the fungating mass of vessels, pyogenic infection and cancer cells, and completely melts the lesion away. The penetration of this x-ray dose in the tumor bed is so small as to be almost negligible in figuring the total dosage.

Electrosurgery and electrodesiccation with curettage have their place in selected cases and are the favored methods of many dermatologists. Because of the high rate of cures and the success of x-ray and radium therapy in our group, electrodesiccation is reserved for precancerous lesions and electrosurgery for radiation failures.

If radiation is to be used, the total dosage must be estimated, a treatment schedule planned for each individual case, and then therapy effectively carried out. One must know the principles of radiation. For 30 years we have used a combination of x-rays and gamma radiation from a radium source, either external or interstitial. This combined use of x-rays of two different qualities, or combined with radium, has been employed by Quick,[10] Smithers,[11] Quimby and Pack,[12] and many gynecologists who combine large dosages of intravaginal gamma radium with 2,000 to 3,000 r units of filtered x-rays. Quimby and Pack [12] as early as 1930 proved experimentally that with a combined use of gamma rays of radium and x-rays one-third more radiation energy was required to produce a skin erythema than was required with x-rays or radium alone. It has been concluded by these investigators that much greater quantities of radiation can be delivered to a carcinoma, with safety to normal tissues, by a combination of two different qualities of radiation than the same total dosage from a single quality.

On this principle has evolved our method of therapy.[13] Briefly, it is 3,000 to 5,000 r of x-rays in divided dosage

to tumors, with the addition of external radium of a dosage of 3,000 to 4,000 gamma r units. This produces excellent results, and the tissue effect does not resemble that of radiation given by a single quality used alone, such as x-rays in divided doses for a total dose of 7,000 r units. This could be predicated upon the fact that there is a much lower number of erythema doses from this combined treatment than if the same dose is given with x-rays alone.

When interstitial radiation is used (and also gamma radiation), 2,000 r units of x-rays, 100 kv., 9 in. distance, half-value layer of 0.9 mm. Al, in one single dose, or, if the area is large, in two divided doses one week apart, are added, giving 6,500 gamma r plus 2,000 r x-rays. For the fungating, largest tumors, the x-rays may be of two different qualities as described previously, both half-value layer 0.9 mm. Al, at 100 kv. and 4.5 mm. Al, at 120 to 140 kv. By combining these various qualities of radiation, our cures are increased to about 98% and 99%.

In treating 700 to 800 skin cancers yearly, the recurrence rate is from 1% to 2%. In 1952, only six cases of ulcerated, infectious lesions resulting from traumatic injury in the old radiation site were seen from radiation therapy given two to five years previously. These are cured in most cases with three to six injections of 100,000 to 200,000 units of penicillin in saline solution under and around the lesion, after procaine anesthesia. After these heavy doses as outlined are administered, care must be exercised in treating the recurrences with desiccation and curettage, since healing will not be rapid. Electrosurgery is the preferred method, and the entire old radiation area should be removed.

Podophyllin, 20% in tincture of benzoin, has a very important place in treatment of the recurrent cancers in our own cases as well as in those of other radiotherapists. Some of these cures have been as dramatic as those reported by Smith and Garrett.[14] Podophyllin seems to be a better agent in old, radioresistant tumors than in fresh, untreated lesions. It is especially satisfactory in radiation cancer in physicians or dentists or in actinic cancer occurring in areas previously over-treated by x-rays for such conditions as acne or eczema. Two dentists and one orthopedic surgeon have been saved from amputation and plastic surgery by this method. The permanence of cure must await time.

Moh's treatment is of value in these cases also, but in the South and Midwest many notorious charlatans and cancer patients themselves have developed and used this method, except that there is no microscopic control or tissue removal as in Moh's method. Therefore it is in disrepute among the profession and the public alike.

SUMMARY AND CONCLUSIONS

Experiences in treating cancer over a period of 18 years, sometimes unsuccessfully, have been briefly reviewed. No patients with any one disease produce more satisfaction and pleasure to the cancer physician than the patients with skin cancer. They need treatment and are pleased with results. Three or four such cases daily help to eliminate the discouragement experienced in treating chronic dermatoses. I conclude by pleading that more centers that have developed a large cancer clientele give thought to short courses each year in radium, x-ray, and other techniques for postgraduate students. Such courses would substitute for the apparent lack of training in some of our dermatological educational institutions and give encouragement to—not belittle—those dermatologists today who are broadening the scope of dermatology, be it in allergy, radiation therapy, or plastic or electrosurgery.

COMPARATIVE PHYSIOLOGY OF THE KIDNEY

Homer W. Smith, Sc.D., New York

We cannot properly speak of physiology, and therefore we cannot speak of comparative physiology, until the time of Harvey. But it is worthy of emphasis that the discoverer of the circulation utilized the comparative method as extensively as any man since his time. It is something of a paradox that Harvey, in observations on the circulation of the blood, failed to challenge the Galenic view on how the blood got from the arteries to the veins but was content to believe that it seeped through the soft organs simply as water seeps through sand.

CONTRIBUTIONS OF MALPIGHI

The microscope, as improved by Galileo, was available in Harvey's time, but either because of lack of acquaintance with the instrument or lack of interest in the finer structure of the body, he failed to use it. It was Galileo's compatriot, Marcello Malpighi, who introduced this instrument into the study of the structure and function of the animal body. Apparently from youth Malpighi had been amusing himself with a microscope of sorts. Shortly after completing his medical training, he began to utilize it so profitably that four sciences now claim Malpighi as their own. With Nehemiah Grew, he pioneered in the study of plants, and his "Anatomy of Plants," published by the Royal Society, entitles him to be considered with Grew as one of the founders of vegetable morphology. Aristotle, Fabricius, and Harvey had all studied the chick embryo, but Malpighi was the first to give an adequate description of how a little white, opaque spot in the hen's egg is transformed into the feathered, living bird, and he is justly called the founder of embryology. At the request of the Royal Society, he undertook an exhaustive study of the silk worm, describ-

ing its life habits, its metamorphosis, its gross structure, and the fine anatomy of its viscera, and giving his name to the Malpighian tubules that constitute the excretory organs of the insects. This treatise, with many other contributions, entitles him to be called the first profound student, after Aristotle, of comparative antomy. It is, however, through his studies of the fine structure of the soft tissues of the body that medical science lays claim to him as the founder of microscopic anatomy.

It was in Malpighi's study of the structure of the lungs, published in 1661, or four years after Harvey's death, that he discovered the capillary circulation, thus completing the gap between the arteries and the veins. Five years later, in a volume entitled "The Structure of the Viscera" (1666), Malpighi described with extraordinary acuity the major microscopic features of the brain, liver, lymph nodes, spleen and kidney. The year before he began his studies of the kidney, Lorenzo Bellini, a 19-year-old Italian youth, had demonstrated by dissections of the deer that what had theretofore been considered to be fibrous strands radiating throughout the kidney were in fact hollow tubes or ducts that radiated inwards from the pelvis to form an elaborately arborized system of caniculi. It was perhaps in tracing Bellini's ducts backwards into their finest ramifications that Malpighi, with a microscope magnifying some 30 times, found that the smallest order of tubes began as spherical bodies or corpuscles, each of which was composed of an elaborate tuft of the capillaries that he had discovered in the lungs. Malpighi satisfied himself that the capillaries were connected with the smallest arteries, and he surmised, if he did not prove, that they were also connected with the efferent veins. He also surmised, but did not establish, that the corpuscles were individually connected with the uriniferous tubes, and that they played an important part in urine formation.

NINETEENTH CENTURY CONTRIBUTIONS

Here, in effect, the matter of renal anatomy rested until 1842, when William Bowman, then a young demonstrator of anatomy at Kings College, London, gave the definitive description of the vertebrate nephron in what is a truly classic paper. It was Bowman's signal achievement to demonstrate that the space around Malpighi's capillary tuft communicates freely with the uriniferous tube so that any fluid separated from the capillaries drains into the latter, but he also described the general structure of the Malpighian corpuscle and of the uriniferous tube in such accurate terms that they could today well serve as an introduction to any text book on renal anatomy. Bowman used a microscope having a magnifying power of approximately 300, but he worked entirely by teasing the kidney apart and without the aid of aniline dyes that had not yet been invented.

Considering that Bowman published only one paper on the kidney, his work was as comprehensive in the matter of comparative anatomy as that of Harvey and Malpighi. Before arriving at his generalizations on renal anatomy, he satisfied himself of the correctness of his descriptions by studying the kidney in man, the badger, dog, lion, cat, mouse, squirrel, guinea pig, horse, parrot, tortoise, boa constrictor, frog, and common eel. Had he happened to examine an aglomerular fish (of which there were several species in the coastal waters of England), his paper, which set the pattern of renal physiology for nearly 100 years, would certainly have had an entirely different cast.

In speculating about the mechanism of urine formation, Bowman logically assigned a different role to the Malpighian corpuscle and to the epithelial tubule. He saw the corpuscle as uniquely designed to separate water from the blood across the *capillary tuft, but he believed* that all the solid constituents of the urine were added to this water as a secretion from the tubular epithelium. His notion of secretion was that of his day, namely, that the secretory epithelium is cast off entirely in the formation of the secretion by a process of disruption or dissolution of the cell. In this view he conceived that the water from Malpighian corpuscle was necessary to wash the disgorged contents of the epithelial cells down the tubule. In this matter he was not dogmatic, however; recognizing that he was endeavoring to demonstrate a doubtful hypothesis by an explanation more doubtful still, he adds that "Parallel lines of inquiry into the anatomical varieties of the Malpighian corpuscles and the uriniferous tubes, and into the chemistry of their secretion in the different kinds of animals and in various stages of their development, could scarcely fail to confirm or to confute what has [here] been advanced."

Bowman failed, in point of fact, to grasp the simple, physiological implications presented by the fine anatomy of the Malpighian corpuscle, a failure that was corrected two years later by Carl Ludwig, professor of anatomy at Marburg, who saw in this corpuscle a beautifully contrived, mechanical device permitting the separation from the blood, by simple process of filtration, of a large quantity of cell-free and protein-free fluid, sufficient in amount to contain all the urinary constituents. Accepting this basic premise of the filtration of a large quantity of fluid, the formation of a concentrated urine must be effected by the reabsorption of a considerable fraction of the filtered water during the passage of the fluid down the tubule. In Ludwig's view, Bowman's secretion by desquamation of the uriniferous epithelium became superfluous and questionably pertinent to urine formation, and Ludwig dismissed it as an improbable hypothesis.

Ludwig's filtration-reabsorption theory met with opposition chiefly from Rudolf Heidenhain, of Breslau, who had discarded the older theory of secretion by cellular desquamation in favor of a continuing intracellular process by which substances, either foreign or native to the blood, were transported from the blood to the urine without breakdown of the epithelium. Thus Heidenhain was perhaps the first to advance the modern view of tubular secretion.

MODERN THEORY OF URINE SECRETION

The differences in Ludwig's and Heidenhain's views assumed the form of seemingly irreconcilable theories and engendered a conflict that persisted throughout the last half of the 19th and into the first half of the present century. The Ludwig filtration-reabsorption hypothesis obtained strong support from Arthur Cushny, then at University College, London, in his 1916 Sidney Ringer lecture, subsequently published in monographic form under the title "The Secretion of Urine." After a careful review of the literature, Cushny failed to see wherein the "secretionists" had established their point, and he marshaled the evidence for the Ludwig hypothesis under the general term of the "Modern Theory of Urine Secretion" because, as he says, his theory rested not on the work of any one man but on the work of many.

Though A. N. Richards had long been interested in the kidneys, as studied in perfusion experiments, it was one of Krogh's papers on the capillary circulation, which had just been published, that launched Richards into his epoch-making micropuncture studies in the frog and Necturus. Between the years 1921 and 1935 Richards and Walker and their co-workers, in a series of brilliant studies that are widely known, translated the Ludwig filtration-reabsorption hypothesis from the realm of theory into fact and laid the foundations for our knowledge of the detailed reabsorptive operations of the proximal and distal segments of the renal tubule.

The question of tubular excretion remained, however, a matter of controversy. That the tubules could excrete some substances, and notably phenolsulfonphthalein, was supported in this country by E. K. Marshall at the medical school of the Johns Hopkins University. In retrospect, I believe that the renal excretion of phenolsulfonphthalein in the dog, as argued by Marshall and Vickers in 1923, is the first definitive demonstration of tubular excretion in any animal, but it was only after Marshall and Grafflin and, independently, Edwards and Condorelli, began their studies on the aglomerular marine fishes that the reality of tubular excretion received general recognition.

Up to the fourth decade of this century, problems in renal [illegible] of a qualitative nature and largely [illegible] answers. After 1932, however, a [illegible] came available for measuring the central operation of glomerular filtration in experimental animals and in man, renal physiology was rapidly transformed into a quantitative subject. Tubular excretion has now been demonstrated to play almost as important a part in urine formation as tubular reabsorption. Both operations, together with glomerular filtration, have become subjects of such wide investigation that we can fairly say that we possess a larger body of precise, quantitative knowledge on the kidney than on any other organ.

RELATION TO EVOLUTION

To summarize the many studies now available on the comparative physiology of the kidney, from the fishes up to man, would be impossible in any short period, and I must be content to emphasize that these studies have paid a great and unexpected dividend in the way of broadening our horizons with respect to the evolution of all the vertebrates, including man. May I recall to your memory the name of Claude Bernard, perhaps the greatest physiologist of the 19th century, and Bernard's epitome that the environment in which *we live is neither air* nor water, but the blood and body fluids that bathe all the tissues. This internal environment, as Bernard pointed out, is characterized by an extraordinary constancy of composition, and it is by virtue of this fact that the animal achieves a free and independent life. This idea of Claude Bernard's has been rated, in respect to physiology, in importance with Darwin's demonstration of evolution for biology. In truth, the two ideas are closely related, because the story of the evolution of the vertebrates is, in essence, the story of the evolution of the internal environment. I need scarcely emphasize to you that it is the kidney that is charged with the synthesis or regulation of this environment, an operation that it carries out in reverse, so to speak, by the circuitous processes of glomerular filtration and tubular reabsorption. Our entire internal environment is, in fact, thrown out of the body by way of the glomerular filtrate some 16 times a day, only to be captured by the renal tubules before it falls to earth, and it is in this process of recapture that the renal tubules perfect and maintain its composition. The progressive evolutionary elaboration of the kidneys to the point where we may live in a fluid the composition of which scarcely suffers any change is a story that can now, in some measure at least, be reconstructed from the data of comparative physiology.

Without this internal environment—that is to say, without the kidney—the first armored fishes could not have invaded fresh water 500 million years ago. It was the physiological crisis engendered by this invasion of fresh water that led to the evolution of the glomerulus as a device enabling the heart to pump water out of the body. Without subsequent improvements in the kidney there could have been no evolution of the air-breathing fishes of the Devonian period, which in subsequent periods supplied the first semiterrestrial amphibious animals, and through the Amphibia, the great dynasties of the Mesozoic reptiles. From these Mesozoic reptiles there came the warm-blooded mammals and such further improvements in the kidney as enabled the mammals to compete with, and finally to supersede, the reptilian forms. Warm-bloodedness fostered the evolution of the brain until, in the primates, the sense of sight came to dominate the sense of smell, culminating in the evolution of the human cerebral cortex, the most elaborate organ in all of animate creation for the mediation of consciousness with its manifold operations of perception, integration, volition, and imagination. When I reaffirm Bernard's thesis that we owe our physiological freedom to the constancy of our internal environment, I am but affirming that both the historic and immediate foundation of this freedom rests in the organ that both historically and immediately supplies us with this stable body fluid.

Harvey, Malpighi, Bowman, Ludwig, and Heidenhain could scarcely have forseen what consequences were to issue from their studies on deer, birds, snakes, frogs, and all manner of animals: but in the revolution that engulfed all biological science after the publication of Darwin's "On the Origin of Species by Means of Natural Selection," these fragments began to fall into a mosaic in which it is seen that, as the physicist John Tyndall said only 15 years after the publication of Darwin's book, "The doctrine of evolution derives man, in his totality, from the interaction of organism and environment through countless ages past. The Human Understanding . . . is itself a result of the play between organism and environment through cosmic ranges of time." Tyndall had, for a physicist, a remarkably comprehensive knowledge of biological science, but in 1874 not much was known about renal function. Otherwise, I believe that he would have mentioned the internal environment, and the kidney, in his philosophic epitome.

TREATMENT OF CHRONIC DISCOID LUPUS ERYTHEMATOSUS WITH QUINACRINE

Harold N. Cole Jr., M.D., Shaker Heights, Ohio, Paul V. Chivington Jr., M.D., Harold N. Cole, M.D.
and
James R. Driver, M.D., Cleveland

The article by Page[1] on the treatment of 18 patients with lupus erythematosus with quinacrine hydrochloride (Atabrine) has initiated widespread interest in the United States regarding this subject. As early as 1940, Prokoptchouk[2] reported the use of quinacrine (Acrichin) in 35 patients with lupus erythematosus and was impressed with its effectiveness. Popoff and Kutinscheff[3] observed remission of lupus erythematosus in six patients treated with quinacrine in 1941. Krynski[4] treated six patients during the period 1940-1945. Pseudoicterus developed in one patient, and another showed a temporary psychic disturbance. He concluded that the method was effective but that the high incidence of side-reactions probably made its more general usage unwarranted. It has since been shown that the American product Atabrine (quinacrine hydrochloride, U. S. P.) probably is less toxic and produces fewer side-effects than Acrichin the Russian product or its German analogue Atabrin.[5] Bispham,[6] in a series of 46,681 patients who received quinacrine for prophylaxis and treatment of malaria, observed only 38 instances of toxic reactions. Agress,[7] in a group of 3,000 patients, reported an incidence of untoward reactions in only one-twentieth of 1%.

In a survey of the toxic manifestations attributable to quinacrine, it is significant that these are almost without exception limited to the skin, hematopoietic system, central nervous system, the liver, and the eye. The cutaneous manifestations described include: (1) lichen planus-like, lichenoid, and eczematoid dermatosis,[8] (2) a toxic exanthem resembling typhus,[9] (3) exfoliative dermatitis,[10] pseudo-icterus,[11] (4) pigmentation resembling that of ochronosis,[12] (5) hemorrhagic capillary toxicosis,[13] and (6) hyperkeratosis of palms and soles.[14] Blood complications include: (1) hemoglobinuria,[15] (2) agranulocytosis,[16] and (3) aplastic anemia.[17] Temporary psychosis and psychoneurotic reactions have been rather frequently reported,[18] and occasionally a case of polyneuritis[19] has been presented. Eye changes include corneal edema,[20] keratitis,[21] and blindness.[22] Hepatic lesions include focal necrosis[23] and toxic hepatitis.[24]

Encouraging preliminary reports on the use of quinacrine in lupus erythematosus have begun to appear in the American literature. Cramer and Lewis[25] reported rapid improvement in six patients. Sawicky and his associates[26] observed prompt and definite improvement in 21 patients, complete clearing in 6, and failure to respond or relapse in 3. Wells[27] in a study of 12 patients reported a good response in 9 and complete clearing in 3, with 3 others considered as therapeutic failures. In one of these, itching and scaling of the palms occurred and in another, dissemination of the cutaneous lesions.

RESULTS OF STUDY

The present study includes 32 patients with chronic discoid lupus erythematosus who had been treated with quinacrine from February, 1952 (table). All but six of these patients had received previous therapy, other than quinacrine, for their condition. The dosage schedule used was 0.1 gm. of quinacrine hydrochloride twice daily for a period of two weeks and 0.1 gm. daily thereafter. Two patients continued on this regimen for one year. Two patients received the drug for only one month. All of the remaining patients were under continuous treatment for at least two months. Cases were classified as severe, moderately severe, and mild, depending on the extent of involvement. Results were evaluated on the basis of three categories: complete clearing, improved at least 50%, and failure. Twelve cases showed complete

Quinacrine Therapy in Thirty-Two Patients with Chronic Discoid Lupus Erythematosus

clearing. Fifteen showed at least 50% improvement, and five were considered failures.

Two patients showed a tendency to relapse while they were being treated with quinacrine. Neither showed a good initial response, and results of treatment in both were ultimately classified as failures. Two untoward reactions were observed. One of these was a severe generalized lichenoid and eczematoid dermatitis occurring after three months of therapy. The patient incidentally showed complete clearing of all lesions, and the drug eruption responded dramatically to cortisone therapy. The second reaction was very mild in character and was indistinguishable from pityriasis rosea. This occurred after four months of therapy.

From this study it would appear that the effects of quinacrine are rapid and dramatic in those cases of chronic discoid lupus erythematosus that will prove amenable to this therapy. In 10 of the 12 subjects in whom complete clearing resulted, the response was noted within three months. This is significant, for it is a generally accepted fact that the incidence of toxic reactions attributable to quinacrine increases with the prolongation of its administration beyond a period of three or four months. Furthermore, it is impossible to definitely state that improvement occurred in any instance in which therapy was continued beyond five or six months. The response to therapy apparently bears no relationship to age, sex, duration, severity, or previous treatment. Thus far, tendency to recurrence or relapse has not been observed in any of these patients in whom the disease ha cleared completely or in patients who have initially show marked improvement.

SUMMARY

A brief review of the preliminary reports on the treat ment of chronic discoid lupus erythematosus with quina crine (Atabrine) hydrochloride is presented togethe with a survey of the toxic effects produced by this dru This study includes a group of 32 patients who ha chronic discoid lupus erythematosus and who wer treated with quinacrine, 0.1 gm. twice daily for two week and 0.1 gm. daily thereafter, for periods ranging fro one month to one year. Twelve patients have shown complete clearing of all lesions. Fifteen patients have show at least 50% improvement, while five have been considered failures. There have been two instances of toxi reaction. One was a severe, generalized, lichenoid an eczematoid dermatosis developing after three months o therapy. The other was a mild, transitory eruption, in distinguishable from pityriasis rosea, occurring afte four months of therapy. Maximum response may b expected early in the course of quinacrine therap usually within three to four months. Thus, if therapy i not continued beyond this period, fewer toxic reaction may be expected. Thus far, relapse or recurrence has n been observed in those patients who showed complet clearing or dramatic initial response to therapy wit quinacrine.

INTESTINAL ANTISEPSIS IN SURGERY

Edgar J. Poth, M.D., Ph.D., Galveston, Texas

The modern concepts of intestinal antisepsis have developed during the past 12 years. Initially, certain sulfonamides, which were poorly absorbed from the gastrointestinal tract, were found to act locally to alter the bacterial flora. These compounds had relatively narrow antimicrobial spectrums, had little effect against the gram-positive organisms, and acted primarily as bacteriostatic agents against the gram-negative bacteria found in the gastrointestinal tract of man. While many of the sulfonamides have some activity, it was not until succinylsulfathiazole (Sulfasuxidine) was used by Knotts, Lee, Inui and myself [1] that the gram-negative flora of the bowel could be altered significantly and consistently. Many sulfonamides were investigated, but ultimately only three could be used as practical intestinal antiseptics. They were, in the order discovered, succinylsulfathiazole,[2] phthalylsulfathiazole (Sulfathalidine),[3] and phthalylsulfacetamide (Thalamyd).[4] Of these three, succinylsulfathiazole was the most promising and satisfactory, because it not only altered the gram-negative flora of the gastrointestinal tract but also aided in th mechanical preparation of the bowel.[5]

These substances had definite disadvantages. The had relatively narrow spectrums, and, being bacteriostatic, they could merely inhibit the multiplication o organisms. It was required, therefore, that the contents of the bowel be evacuated by mechanical cleansing o the irregular mucosal surface of the bowel to remove viable bacteria. This procedure requires a considerable length of time and is not effected consistently and satisfactorily in less than seven days.[6]

The antibiotics were subsequently studied as intestinal antiseptics. Streptomycin was the first,[7] and was immediately found unsatisfactory because of the rapid development of resistant organisms.[8] The gastrointestinal tract, with its complex structure, fecal content, and subjection to reinfection by oral ingestion of contaminated material provides an excellent site for the development of resistance.

When chlortetracycline (aureomycin) first became available in very limited quantities, it was used at the University of Texas Medical Branch in an attempt to treat poliomyelitis during the summer of 1948. I studied the stools of the patients treated and concluded that chlortetracycline was not an acceptable intestinal antiseptic.[9] The flora was altered on occasions, but not consistently,

and it was soon demonstrated that Micrococcus pyogenes var. aureus (Staphylococcus aureus) would frequently grow out. Subsequently, this substance was investigated by Pulaski, Connell, and Seeley,[10] who also concluded that, in comparison to other available intestinal antiseptics, chlortetracycline possessed no advantages. Dearing and Heilman [11] published material in 1950 showing that chlortetracycline rapidly altered the bacterial flora quite satisfactorily, and it was proposed as an intestinal antiseptic.

Oxytetracycline (Terramycin) [12] was also proposed as a wide spectrum intestinal antiseptic with bactericidal properties. It possessed the same disadvantages as chlortetracycline. With continued use, it was noted that, even when chlortetracycline and oxytetracycline were not used as intestinal antiseptics, frequently nausea, vomiting, and bloody diarrhea developed.[13] Occasionally, a choleriformic type of disease would develop, with pseudomembranous colitis followed frequently and rapidly by death.[14] Only recently has it been demonstrated that this choleriformic disease is due to the overgrowth of Micrococcus pyogenes on approximately the third or fourth day when the other organisms are diminished and the naturally occurring antagonists of the staphylococci removed (fig. 1).[15] The population of staphylococci in the gastrointestinal tract of man is usually quite small.

I [16] first used neomycin as an intestinal antiseptic in December, 1949. It was immediately realized that this substance had strong bactericidal properties, rapidly eliminated bacteria from the gastrointestinal tract, and gave promise of being an excellent intestinal antiseptic. The response of the first 30 patients who were treated with neomycin alone was excellent. There was no indication that any organisms survived. It was early recognized that the yeasts grew out in large numbers immediately after elimination of the bacteria. Shortly after this series of patients was studied, three instances of Aerobacter aerogenes resistance were observed in rapid succession.[17] The incidence of early Aerobacter aerogenes overgrowth varied somewhat with the season of the year and was particularly likely to develop in this section of the United States during the summer months. Approximately 10% of the persons treated had persistent overgrowth of this organism. Obviously, this complication would reduce materially the value of neomycin as an intestinal antiseptic. Thereafter, phthalylsulfathiazole was given in conjunction with neomycin to inhibit the outgrowth of Aerobacter aerogenes. This combination closely approaches the requirements of an ideal intestinal antiseptic.

The ideal intestinal antiseptic should have the following properties [18]: (1) broad bacterial spectrum; (2) low toxicity for the host; (3) chemical stability in the presence of digestive ferments; (4) capacity to prevent development or overgrowth of resistant bacterial variants; (5) rapidity of action; (6) limited absorption from the gastrointestinal tract; (7) activity in the presence of foods or other foreign substances, thereby allowing adequate intake of foods and fluids; (8) capacity to aid in the mechanical cleansing of the bowel without causing dehydration; (9) inability to irritate the gastrointestinal mucosa; (10) noninterference with tissue growth and repair; (11) low dosage requirement; (12) solubility in water; (13) palatability; (14) inhibitive activity on excessive growth of fungi; and (15) restricted use, i. e., use only as an intestinal antiseptic. A satisfactory regimen of intestinal antisepsis must not permit the development of resistant pathogenic strains of bacteria or result in extensive absorption of the agent or agents from the gastrointestinal tract.

If a substance to be used as an intestinal antiseptic is absorbed even moderately from the gastrointestinal tract, the incidence of untoward secondary reactions will greatly limit its use in patients to be subjected to extensive operative procedures. Intestinal antiseptics, to be effective, must be given in such large quantities that, if absorbed, the untoward reaction rate will be prohibitively high.

A substance that is not absorbed from the gastrointestinal tract, is chemically stable, and is not destroyed in the bowel by digestion will remain active in the bowel until evacuated. This property is particularly desirable, because then the effect will continue during the period of postoperative paralytic ileus when nothing can be administered by mouth. The combination of neomycin and phthalylsulfathiazole fulfills these major requirements surprisingly well.

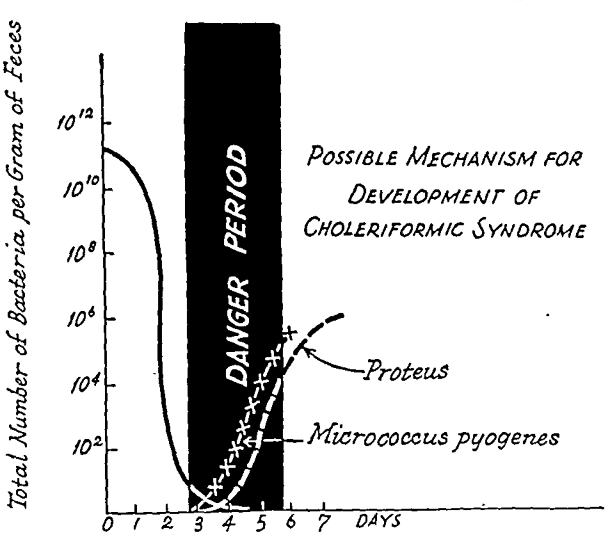

Fig. 1.—Representation of what may be the sequence of events when the so-called choleriformic syndrome develops following oral administration of chlortetracycline or oxytetracycline. When the bacterial flora is markedly suppressed on the third to fourth day, Proteus organisms grow out quite regularly and may cause diarrhea. Should a resistant Micrococcus pyogenes develop that produces a potent enterotoxin, then nausea, vomiting, bloody diarrhea, hyperpyrexia, collapse, and death may result. This simplified diagram cannot present all the possibilities.

An antibacterial agent that is used solely for intestinal antisepsis is less likely to encounter resistant strains of bacteria because of the lesser likelihood that resistant strains will become common as a result of widespread administration. The field of intestinal antisepsis has developed to where the search is no longer for new intestinal antiseptics but rather for intestinal antiseptics that are superior to those available or for a substance whose use will be restricted to intestinal antisepsis.

ABSORPTION AND EXCRETION OF NEOMYCIN

Studies were conducted to determine to what extent neomycin is absorbed from the gastrointestinal tract of man, what blood levels are maintained, and the rapidity of excretion of the antibiotic in the urine. Following the oral administration of a single 1 gm. dose of neomycin to a person with a normal gastrointestinal tract, hourly blood specimens were taken for the first six hours and then every four hours thereafter for 48 hours. Ordinarily, no neomycin could be detected in the serum. Occasionally, some antibacterial activity against the spores of Bacillus subtilus could be demonstrated in the undiluted serum. The urine was quantitatively collected until assay of the stools showed that they no longer contained neomycin and then the urine was assayed for neomycin. Excretion by the kidneys averaged 3% of the ingested dose. Blood specimens assayed following a maintenance dose of neomycin of 1 gm. every four hours for three days yielded only slight antibacterial activity.

BACTERICIDAL ACTIVITY OF NEOMYCIN

Aside from the fact that neomycin has only slight activity against Shigella organisms and the fact that in a certain percentage of patients a resistant strain of Aerobacter aerogenes will develop following its oral administration, the bacterial spectrum of this substance makes it particularly suitable as an intestinal antiseptic. No bacteria can be cultured from a 10% suspension of human feces 30 minutes after the addition of neomycin in a concentration of 500 mcg. per milliliter. A concentration of 10,000 mcg. of neomycin per milliliter can be maintained in the gastrointestinal tract of man under therapeutic conditions.

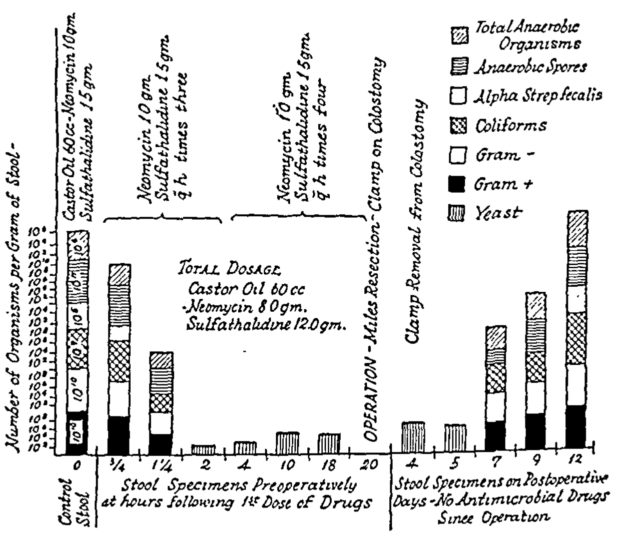

Fig. 2.—Illustration of the rapid and sustained antimicrobial action following administration of neomycin and phthalylsulfathiazole (Sulfathalidine) to a patient without bowel obstruction preoperatively.

Following these observations, experiments were conducted to determine the degree to which neomycin would protect mice against peritonitis resulting from introduction of a suspension of feces into the peritoneal cavity. Mice weighing 20 gm. were inoculated with 1 ml. of a 10% suspension of human feces. These animals began to die within three hours after inoculation. Almost all of the animals were dead in 12 hours, and none survived at the end of 24 hours. If these animals received intraperitoneally a tolerated dose of neomycin within the first hour after inoculation, however, the survival rate was 100% as contrasted to a mortality of 100% in the untreated animals. The inoculum of feces received by the mice corresponds to 400 gm. or 4,000 cc. of the 10% suspension given to a man weighing 80 kg. It is inconceivable that a person could survive, regardless of any therapeutic procedure, following the introduction of such a large quantity of highly contaminated material with its accompanying foreign matter into the peritoneal cavity.

Even though the findings in the mouse must not be carried over directly to man, these observations give an indication of the efficacy of this antibiotic. It has been repeatedly shown to be impossible to grow bacteria from specimens removed from the bowel at the time of operation 30 minutes after the gastrointestinal tract of man is flooded with a 1% neomycin solution.

STABILITY OF NEOMYCIN IN THE GASTROINTESTINAL TRACT OF MAN

Since neomycin is so poorly absorbed from the gastrointestinal tract, it becomes of interest to determine how long this antibiotic will remain active in this environment (fig. 2). Patients who had undergone abdominoperineal resection of the rectum with the colostomy kept clamped off until the fourth postoperative day were selected for studying the persistence of the bactericidal activity of neomycin in the bowel. These patients had been prepared with neomycin and phthalylsulfathiazole, and just prior to operation no viable organisms could be isolated from the feces. Postoperatively the patients received no antibacterial drugs either by mouth or parenterally. All stools were cultured following the removal of the colostomy clamp. Ordinarily considerable quantities of feces were passed immediately following removal of clamp. Usually no viable bacteria could be cultured from the stool for as long as six to seven days postoperatively. If a primary anastomosis was done, the third postoperative stool usually showed a few organisms and the normal bacterial flora ordinarily reestablished itself in the course of an additional two or three days. There was no growth of bacteria during the period of paralytic ileus.

OUTGROWTH OF YEASTS

It has been observed that yeasts grow out in great numbers when the bacterial population is reduced to low numbers by the antibiotics. The development of bloody diarrhea following the oral administration of chlortetracycline and oxytetracycline was considered to be due to Monilia infection. Considerable doubt is cast on this supposition, however, when it is realized that oral administration of neomycin results in a greater reduction of the bacterial population and a greater outgrowth of yeasts without the development of bloody diarrhea.[10] No complications due to the outgrowth of yeasts have been observed in 526 persons treated with neomycin orally.

These yeasts consist largely of Candida albicans, with occasionally large numbers of Actinomyces being present. The hazard existing because of the presence of these yeasts should not, however, be disregarded as possible causes of rare and bizarre complications. Bacteria hold the growth of yeasts in check, and it would be helpful if a strain of nonpathogenic organisms resistant to the intestinal antiseptic could be maintained in the bowel. The relatively nonpathogenic alpha Streptococcus fecalis is not depressed by the sulfonamides, and these organisms effectively suppress the yeasts. No suitable nonpathogenic organism has been found that will continue to grow following the administration of neomycin. No satisfactory means has been found to suppress the yeasts, but there seems to be considerable doubt that yeasts cause complications except in rare instances, possibly in extremely debilitated or moribund persons.

INFLUENCE OF INTESTINAL ANTISEPSIS ON HEALING

Healing of the bowel must not be retarded by intestinal antiseptics either because of their direct contact with the tissues or because of unfavorable secondary influences such as may result from enterotoxins produced by the Micrococcus pyogenes overgrowth that occasionally follows the oral administration of chlortetracycline and oxytetracycline. We have been unable to show any evidence of vitamin K deficiency following the prolonged administration of succinylsulfathiazole, phthalylsulfacetamide, or neomycin. It is conceivable that the clotting mechanism may be altered by the prolonged administration of neomycin and phthalylsulfathiazole and a purified diet such as protein hydrolysate and carbohydrates given either orally or intravenously.

It has been demonstrated experimentally that succinylsulfathiazole, phthalylsulfathiazole, streptomycin, and neomycin do not retard healing.[20] In fact, healing proceeds rapidly and simulates primary tissue repair.

PROPERTIES AND CHARACTERISTICS OF PROPOSED INTESTINAL ANTISEPTICS

Following are brief descriptions and conclusions as to the value of substances that have been proposed as intestinal antiseptics.

Sulfaguanidine.[21]—Sulfaguanidine has very limited antiseptic activity. It is readily inhibited in the presence of ulcerating lesions in the gastrointestinal tract. It is slow in its action, and it is absorbed in appreciable quantities. Sulfathiazole and sulfaguanidine are absorbed about equally from the gastrointestinal tract. It was found that approximately one-fourth of the patients who received sulfaguanidine as an intestinal antiseptic had untoward toxic reactions characteristic of reactions to the sulfonamides. It is not recommended as an intestinal antiseptic.

Succinylsulfathiazole.[22]—Succinylsulfathiazole is not readily absorbed from the gastrointestinal tract. It rather consistently inhibits the growth of gram-negative organisms, which are normal inhabitants of the gastrointestinal tract of man, without evidence of the development of resistance. Untoward reactions characteristic of sulfonamide compounds develop in approximately 1% of the treated patients. Since succinylsulfathiazole is a bacteriostatic agent, it must be administered for approximately seven days before its full effect is obtained. It tends to make the stools soft and aids in the mechanical preparation of the gastrointestinal tract. It is the most satisfactory of the bacteriostatic sulfonamides available as an intestinal antiseptic.

Phthalylsulfathiazole.—Compared to succinylsulfathiazole, phthalylsulfathiazole has very much the same properties. It is approximately twice as effective gram for gram. It has the undesirable property that it tends to cause the stools to have a ropy, tenacious consistency, which makes the evacuation and cleansing of the bowel somewhat difficult. It possesses the advantage over succinylsulfathiazole, however, that it is more effective in the presence of a watery diarrhea. Toxic reactions develop in less than 1% of the treated patients.

Phthalylsulfacetamide. — Phthalylsulfacetamide has much the same properties as succinylsulfathiazole and phthalylsulfathiazole. It is, however, absorbed to a much greater degree than the previous two sulfonamides. The extent of this absorption varies greatly. It can be expected, therefore, to give rise to a relatively larger number of toxic reactions.

Streptomycin.—Streptomycin acts rapidly, removing almost all organisms in 24 to 48 hours of oral administration. This is followed unfortunately by the rapid development of resistant strains within three to four days. This antibiotic is sparingly absorbed from the gastrointestinal tract. Following oral administration, there is no toxicity. It cannot be recommended as an intestinal antiseptic because of the rapid development of resistant strains of organisms. It is of no value in the postoperative paralytic ileus phase.

Chlortetracycline.—Chlortetracycline is a broad spectrum antibiotic with bactericidal properties. It removes bacteria from the gastrointestinal tract moderately rapidly, but unfortunately there is outgrowth of resistant organisms. Micrococcus pyogenes and Proteus organisms appear on about the third or fourth day following suppression of the coliform bacteria. If Proteus organisms grow out first, the Micrococcus pyogenes will be inhibited. Should the Micrococcus pyogenes grow out first, serious complications may result. About 30% of staphylococci are now resistant to chlortetracycline, and some 40% of these organisms produce a potent enterotoxin. This enterotoxin is capable of producing the so-called choleriform syndrome, consisting of vomiting, bloody diarrhea, hyperthemia, and collapse. The course may be rapidly fatal, even though the complication is recognized early and proper treatment is instituted immediately.

Furthermore, the antibiotic is absorbed and not retained in the gastrointestinal tract during the postoperative paralytic phase. It is not recommended as an intestinal antiseptic.

Oxytetracycline.—Oxytetracycline has very much the same properties as chlortetracycline. For the same reason, it is not recommended as an intestinal antiseptic.

Chloramphenicol.—Chloramphenicol has limited activity. Because of its toxic reaction and high degree of absorption from the gastrointestinal tract, it is not recommended as an intestinal antiseptic.

Neomycin.—Neomycin is a broad spectrum antibiotic with bactericidal properties. It is capable of sterilizing the gastrointestinal tract in two to three hours when administered together with castor oil. After contact with feces for 15 minutes in concentrations that are readily maintained in the gastrointestinal tract, no viable bacteria can be isolated. This antibiotic has only limited activity against Shigella organisms. Aerobacter aerogenes grows out in approximately 10% of cases. Neomycin is not recommended as an intestinal antiseptic when used alone.

Neomycin and Phthalylsulfathiazole.—The administration of neomycin and phthalylsulfathiazole combined gives excellent results. The phthalylsulfathiazole inhibits the outgrowth of Aerobacter aerogenes. This combination is undoubtedly the best available material for intestinal antisepsis now available. Action is maintained as long as the drugs are retained in the gastrointestinal tract. Both of these substances are absorbed from the gastroenteric tract to a limited degree.

CLINICAL APPLICATION OF NEOMYCIN AND PHTHALYLSULFATHIAZOLE

Patients can be divided into three groups. The first consists of persons to whom purgatives may be given. Partial obstruction is present in the second group, necessitating more cautious handling and gradual decompression of the bowel. The third group is comprised of patients having acute or complete intestinal obstruction, stab wounds, and gunshot wounds necessitating urgent abdominal exploration. In this group preoperative preparation directed toward decompression of the bowel or alteration of the intestinal flora is not feasible. Following are the outlines of the usual treatment in these three groups:

Group 1.—The complete preparation requires 20 hours in group 1. Measures include a low residue diet. At 1 p. m. 60 cc. of castor oil, 1.0 gm. of neomycin, and 1.5 gm. of phthalylsulfathiazole are given. At 2 p. m., 3 p. m., and 4 p. m. 1.0 gm. of neomycin, and 1.5 gm. of phthalylsulfathiazole are given. At 8 p. m., 12 midnight, 4 a. m., and 8 a. m., or every four hours until operation, 1.0 gm. of neomycin and 1.5 gm. of phthalylsulfathiazole are given. The operation is performed at 9 a. m.

Group 2.—In group 2 the period of preparation is determined by the length of time required to decompress the bowel. No purgation is necessary. Gastric suction is continued until the bowel is decompressed and gas is passed. Neomycin in doses of 1.0 gm. and phthalylsulfathiazole in doses of 1.5 gm. are given for a minimum of 24 hours or until optimal mechanical preparation is obtained.

Group 3.—In group 3 urgent surgical treatment is required as soon as the general condition of the patient warrants. Should it become necessary to resect the bowel, do primary anastomoses, or close large defects in the bowel, decompression is performed transabdominally and the bowel is flooded with 1% neomycin solution. Frequently a liter of solution is injected into the lumen of the small and large bowels. Adults will tolerate the introduction of 2.0 gm. of neomycin into the peritoneal cavity. Neomycin and phthalylsulfathiazole contained in the bowel will continue to be active throughout the period of postoperative paralytic ileus.

COMMENT

Intestinal antisepsis has a definite place in our medical armamentarium. Experimentally it can be shown that the healing of the wound at the line of anastomosis is changed from the secondary healing of an infected contaminated wound to healing that closely resembles primary repair. The experimental demonstration that 50% of animals will survive following ligation of the blood supply to segments of bowel of sufficient length to caus the death of all untreated animals is again strong ev dence that removal of pathogenic bacteria from th lumen of the bowel gives considerable protection to ti sues with markedly impaired blood supply.

Postoperative peritonitis or disruption of the sutu line and fistula formation has not occurred in a sing patient under my care since 1941, when succinylsulf thiazole became available. Furthermore, wound infe tions, especially those caused by the coliform organis have become extremely rare, even though open sutu of bowel is done regularly.

The open suture method of bowel anastomosis can done safely following proper application of intesti antisepsis. This permits more accurate approximation bowel edges, with less tension, a better blood supply, l edema, and uncomplicated healing.

The temperature seldom rises more than 1 degree the first day after resection and primary anastomosis the colon and remains normal thereafter. The entire co valescence is much simplified.

Dixon and Benson [23] showed that, after closure of colostomy, 80% of wounds healed primarily when t patient was prepared with succinylsulfathiazole as co pared to 8% when intestinal antiseptics were not us Pemberton, Black, and Maino [24] showed a change mortality due to peritonitis following surgery of the lar intestine from 6.1% in 1934-1940 to 1.6% in 194 1942 and in 1.4% in 1942-1943 after intestinal antis sis was practiced.

The practice of intestinal antisepsis does not prolo the period of preoperative preparation. As soon as t bowel can be prepared mechanically, it can now be p pared bacteriologically. It does not require so much an hour's contact of a readily attained and maintain concentration of neomycin with the fecal contents of t bowel to render them essentially sterile. Phthalyls fathiazole given at the same time will inhibit the o growth of Aerobacter aerogenes.

These intestinal antiseptics will remain in the bo during the period of postoperative ileus and contin their effectiveness. Once bowel evacuations are reesta lished, the drugs can be again administered. They ne not be given postoperatively except when defects a closed or primary anastomoses of the bowel are p formed.

It is most inconvenient that the aspects of intesti antisepsis are so changeable, as they are in the entire fie of antibacterial therapy. What is fact today must be mo fied tomorrow, because the variables will have chang again. No sooner is an effective antibacterial age found than a new group of resistant variants appear.

Succinylsulfathiazole, with its slow action and narro bacterial spectrum, has continued to be an effecti intestinal antiseptic against most of the pathogen organisms in the gastrointestinal tract of man. The u of succinylsulfathiazole is so limited that a widesprea evolution of resistant organisms has not occurred. F this reason and because resistant pathogenic organis have developed following the use of many of the ant biotics, succinylsulfathiazole has remained useful in i testinal antisepsis and may become even more importa if resistant variants of pathogenic organisms develop against such a valuable intestinal antiseptic as neomycin.

Neomycin has continued to be as effective as an intestinal antiseptic in this community as when it was first used in December, 1949. A seasonal variation is noted when dogs are treated. During the hot, humid summer months in Galveston, no substance or combination of substances has been found that will appreciably lower the microbial population of the dog's intestinal tract. There is less tendency toward resistance in man. However, an Aerobacter aerogenes resistant to neomycin was first encountered during the summer of 1950.

A number of hemolytic and nonhemolytic streptococci are fairly resistant to neomycin. Under conditions of preparation of the bowel, the alpha Streptococcus faecalis, the usual inhabitant of human bowel, disappears very promptly and completely and does not reappear during the course of treatment. It is possible that resistant streptococci may eventually be found in certain communities. Attention is called to the fact that bacitracin is highly effective against streptococci, and it is only sparingly absorbed from the bowel. The occasion may arise when it will be desirable to add bacitracin to the combination of neomycin and phthalylsulfathiazole. Also polymyxin B is poorly absorbed from bowel and is quite active against Pseudomonas organisms.

It would be most helpful if the use of an antibiotic such as neomycin could be restricted to intestinal antisepsis. Neomycin ointment is being used rather widely for topical therapy in skin conditions, and it is not unlikely that many resistant variants will soon appear, with the resultant diminution of the value of neomycin as an intestinal antiseptic. In all probability, however, resistance will first become evident following the use of the ointments, and perhaps this widespread topical application will be discontinued before resistant streptococci occur in the bowel.

Chlortetracycline and oxytetracycline have rapidly become useless as intestinal antiseptics because their wide and frequent general use has resulted in 30% of Micrococcus pyogenes being resistant variants. Since 40% of these organisms produce potent enterotoxins, the overgrowth of these organisms in the intestinal tract too frequently establishes the serious complication called the "choleriformic syndrome" following oral administration of chlortetracycline and oxytetracycline.

With these considerations in mind, it is proposed that the use of neomycin be restricted to intestinal antisepsis in combination with phthalylsulfathiazole or other antibacterial agents that are poorly absorbed from the gastrointestinal tract. It may not be amiss to suggest that the A.M.A. Council on Pharmacy and Chemistry make recommendations as to the uses to which various antibiotics should be restricted. Especially the use of these valuable and specific therapeutic agents should be discouraged when they are not absolutely indicated.

CONCLUSIONS

Intestinal antisepsis is worth while. Neomycin and phthalylsulfathiazole (Sulfathalidine) given simultaneously are the best intestinal antiseptics now available.

COUNCIL ON FOODS AND NUTRITION

WITHDRAWAL OF ACCEPTANCE OF SMA CONCENTRATED LIQUID

The Council on Foods and Nutrition has authorized the publication of the following statement.

James R. Wilson, M.D., *Secretary.*

After thoughtful consideration, the Council on Foods and Nutrition withdrew its acceptance of SMA Concentrated Liquid of the Wyeth Laboratories, Inc., on Oct. 8, 1953. In May, 1953, attention was called to the occurrence of convulsions in certain infants fed on a new formula of SMA Concentrated Liquid. This product was withdrawn from the market and replaced with another formula. However, reports of convulsions were again called to our attention. After this, vitamin B_6 was added to the formula. The evidence thus far available does not satisfy the Council that this simple addition corrects the basic difficulty. The problem needs further study. The Council will be pleased to consider new evidence concerning the acceptability of SMA Concentrated Liquid. SMA Powder remains a Council accepted product.

The following products have been accepted as conforming to the rules of the Council.

James R. Wilson, M.D., *Secretary.*

Heinz Junior Marcaroni and Cheese.

Ingredients: Marcaroni, cheese (cheddar), whole milk powder, cake flour, salt, and water.

Analysis (submitted by manufacturer).—Total solids 14.85%, moisture 85.15%, ash 1.12%, fat (by acid hydrolysis) 2.68%, protein (N × 6.25) 2.95%, crude fiber 0.26%, total sugar as sucrose 1.03%, natural reducing sugar 1.07%, acidity (as lactic) 0.13%, starch 6.64%, and salt 0.79%.

Vitamins and Minerals	Per 100 Gm.	
Carotene	25	I. U.
Thiamine	16.5	mcg.
Riboflavin	70	mcg.
Niacin	0.139	mg.
Calcium	78	mg.
Phosphorus	49	mg.
Iron	1.5	mg.
Copper	1.3	mg.

Calories.—0.67 per gram; 19.0 per ounce.

Use.—For use as a transition food for infants from semiliquid foods to adult foods.

Heinz Strained Rice and Cheese.

Ingredients: Cheese (cheddar), rice, wheat flour, cream, whole milk powder, salt, and water.

Analysis (submitted by manufacturer).—Total solids 15.26%, moisture 84.74%, ash 1.06%, fat (by acid hydrolysis) 4.12%, protein (N × 6.25) 2.81%, total sugar as sucrose 0.76%, natural reducing sugar 0.86%, crude fiber 0.06%, acidity (as lactic) 0.11%, starch 6.28%, and salt 0.79%.

Vitamins and Minerals	Per 100 Gm.	
Thiamine	14.1	mcg.
Riboflavin	77.0	mcg.
Niacin	0.124	mg.
Calcium	85.0	mg.
Phosphorus	58.0	mg.
Iron	0.20	mg.
Copper	0.013	mg.

Calories.—0.76 per gram; 21.6 per ounce.

Use.—For use as a transition food for infants from milk to semiliquid foods.

STATE PHYSICIANS PLACEMENT ACTIVITIES

Physicians placement activities by state associations and by the American Medical Association have increased during 1953. This work in the A.M.A. is under the direction of the Council on Medical Service's Committee on Extension of Hospitals and Other Facilities. The committee began the year by stepping up its own work. States have been encouraged by the committee to improve the data on openings, to expand their contacts with sources of physicians, and to work more closely with communities needing a physician. The committee, in turn, has for the first time sought to publicize the services offered to physicians and communities by the A.M.A. and has developed a periodic reporting system for checking on both openings and requests for placements. As a part of this work, two regional conferences were scheduled during the year. The first was held in Memphis, Tenn., in March, the second in Asheville, N. C., in September.

Ten years ago relatively few states offered organized service in this field. Today there are 43 state physician placement services behind the communities seeking adequate medical aid. The amount and form of activity varies with the state but whether or not the state carries on such a program the placement service of the A.M.A. stands ready to assist both communities and physicians. If an active organization exists in the state, the A.M.A. serves as a clearing house, passing on to the states the requests that are received and providing information for physicians who are interested in more than one state.

What is meant by a good physician placement service? The director of the Virginia Council on Health and Medical Care offers this definition: "By a good service I mean one where requests from communities are carefully investigated to establish the need for a doctor; where there is personnel available to meet with community groups to give them the ABC's of getting doctors; where up-to-date information is sent monthly or at least quarterly to communities on available doctors and detailed information to doctors on communities; where periodic follow-up visits are made to communities to encourage them and answer their questions; and where contact is kept with the community and the local doctor to make certain that the new relationship is not spoiled by misunderstandings, and that the doctor, once located, stays."

The service in Virginia, under the direction of Edgar J. Fisher Jr., is making great strides toward alleviating the shortage of doctors in the rural areas. A direct request for guidance must come from an individual or group in the community. When that request is presented, an all-out effort is made toward securing the services needed. Success stories of such communities as Forest, Huddleston, and Montevideo, Va., are a few examples of how a united effort resulted in providing needed medical aid. Money was raised in each of these areas to build a clinic; adequate facilities brought, in some cases, not one doctor but two. According to various physician placement service directors, "a community can have necessary medical care if the citizens want it, are willing to work for it, and have the know-how to get it." Persons are usually willing to work for the things they really want.

The first time a physician is secured by a community a guiding hand may be needed. Those who operate a state placement service know their state—the communities, the medical persons, and the roads—and most of all they have had experience with the problems of obtaining a physician for a community. They are in contact with the medical schools in the area and the hospitals approved for the training of interns and residents; to their office go the letters of physicians who seek a practice in that state. The placement service of the Illinois State Medical Society, under the guiding hand of Harold M. Camp, M.D., puts strong emphasis on the need of a community. Cognizance is taken of the location of the community requesting assistance in securing a physician. Because good roads make distances a small consideration, communities as near as 10 miles to medical facilities are encouraged to use the existing medical aid. Communities are not encouraged to seek a physician when it is apparent that what they really are seeking is a "first aid man." This well-organized service has ample facilities for assisting both communities and physicians. Five class A medical schools, a generous loan fund for training prior to internship, and associated programs, achieved through the Illinois State Medical Society, are additional aids in meeting the medical needs of the state.

In Missouri, Mr. Raymond McIntyre, the field secretary of the state medical association, makes a personal visit to all communities that request assistance in obtaining a physician. His visit is highly valuable to the community; in telling what they have and what they need, the community takes inventory. This may be the first step toward the location of a home and a place to practice for the physician. The prior approval of local medical practitioners is sought before the community is listed as needing an additional practitioner. Such first-hand information facilitates the office work that will follow, when listings are sent to the physicians and when the inquiring physicians visit the office.

Most placement services put strong emphasis on personal contact, both with the physician and, where personnel permits, with the community. Written records of this information are highly important; mental files are lost for all practical purposes when a change in personnel occurs. In consulting such placement services as those in Texas, Ohio, Michigan, North Carolina, New York, and Virginia, it can be seen that much of their success can be attributed to the complete and up-to-date file systems. Placement service is for the assistance of communities seeking a physician; a physician seeking an assistant; an industry, college, institution, or public health group seeking a physician; and those seeking the services of a specialist, which means this service is available to the physicians seeking such openings. During the past year the state-operated physician placement services have handled requests from more than 2,700 physicians seeking a location. Since some physicians make inquiry in more than one state, duplications occur in this figure. In addition, 702 communities have sought the aid of these services. A strong placement service under the state medical association is visible proof that organized medicine is making an effort to help persons help themselves to adequate medical care.

RESECTION OF ANEURYSMS OF ABDOMINAL AORTA AND RESTORATION OF CONTINUITY WITH HOMOGRAFT

DeBakey and Cooley [1] point out that the survival period in cases of aortic aneurysms is relatively short, ranging from six months to two years in well over half of the patients, with only a few patients living more than several years after the onset of symptoms or establishment of diagnosis. The various attempts to treat aortic aneurysms in the past, whether by an attempt to promote thrombosis and fibrotic organization, by introduction of foreign material into it, or by the wrapping method to encourage periarterial fibroblastic reaction, have not given encouraging results. Extirpation of the aneurysm with restoration of blood flow appeared as the only logical surgical therapy in these cases.

Gross and his associates,[2] in their extensive experimentation with arterial grafts in dogs, advanced the principle that a satisfactory solution to the problem of bridging a gap in large arteries or in the aorta would lie in the direction of providing a vascular graft that would be viable, would resemble the normal vessel after implantation, could withstand intra-arterial pressures, would not cause thrombosis, and would not set up serious reaction in the original tissues. Experiments by Carrel and by Guthrie had demonstrated that transplantation of fresh arterial grafts from one animal to another had shown degrees of survival. Three main factors, according to Gross, that might influence the success or failure of an arterial graft, were (1) the viability of the vessel at the time of implantation, (2) the degree of immunological reaction between the host and the graft, and (3) the technique employed in making the anastomosis.

After much experimentation, Gross and associates developed a method for the preservation of arterial segments. This consists of storage of vessels in temperatures just above freezing (1 to 4 C) and immersing them in a mixture of 10% homologous serum in a balanced salt solution to which were added a buffer, a pH color indicator, and streptomycin and penicillin. Vessels to be stored have been removed from donor animals between one and four hours after death and have been kept as long as 42 days before they were successfully transplanted into other dogs. Tissue culture studies have shown that viability is maintained for 35 to 40 days in blood vessels stored in this manner. Segments of arteries or aortas have been secured from persons who have died suddenly without sepsis. These vessels have been stored in the manner described and have subsequently been used for human patients, when the need arose, to bridge gaps in large arteries. Segments of such preserved arteries or aortas have been grafted by Gross and his associates into human subjects, with promising results.

In 1951 Dubost [3] reported a case of abdominal aneurysm in which the aneurysm extended from below the origin of the renal arteries downward to involve the aortic bifurcation. He resected the aneurysm and reestablished the continuity of the aorta by utilizing a graft of human aorta preserved for 15 days in the medium as suggested by Gross. An end-to-end anastomosis was performed; the left common iliac and the left hypogastric arteries were sectioned; and the left common iliac was anastomosed to the graft by an end-to-side anastomosis. Three weeks later the patient was able to walk and had excellent pulsation in both legs.

DeBakey and Cooley report, in a recent communication,[1] on seven patients in whom aortic aneurysm was resected and the normal blood flow was restored by means of an aortic homograft. The aneurysm in six patients was of arteriosclerotic origin and in one of syphilitic origin. The aneurysms were all located in the segment of the aorta below the origin of the renal arteries. The age of the patients ranged from 47 to 74 years. There was one death in this series. The rest of the patients tolerated the operation well and have shown excellent early results. These authors also report on five additional cases in which the same procedure was performed with no fatalities and no complications. The aneurysms were all of arteriosclerotic origin and involved the bifurcation, which therefore had to be resected. Anticoagulants have not been used in these operations. The period of aortic occlusion varied from 48 to 102 minutes. The anastomotic procedure was found to be technically feasible in all of their cases despite rather extensive atheromatous changes in some. Even though the immediate results of the resection of these aneurysms were highly successful, it is perhaps much too early to predict the ultimate results.

THE EFFECT OF ISONIAZID ON THE EMOTIONS

Because there has been some controversy regarding the effect of isoniazid on the emotions of tuberculous patients, an examination of the available facts is in order. According to one of the earlier reports [1] the apathy and drowsiness characteristically seen among many of the acutely ill tuberculous patients were completely eliminated by the second week of treatment in all instances. Some of these patients even became disciplinary problems before any objective signs of improvement could be noted. These and other workers published reports in which similar observations were made, but this aspect of treatment with isoniazid was not confirmed in a later report.[2]

The attitudes and emotional reactions of the patients are important factors in the treatment of tuberculosis, as was recognized by Osler, who said, "It is just as important to know what is in a man's head as what is in his chest if you want to predict the outcome of his pulmonary tuberculosis." For this reason Calden [3] set about to evaluate the attitudes of tuberculous patients and concluded that the sentence completion method, a projective technique widely used by clinical psychologists in a variety of hospital settings, modified to fit this group of patients, was highly valid.

Lorenz and co-workers [4] in an effort to reach a definite conclusion regarding the effect of isoniazid on the emotions of tuberculous patients studied 15 male patients selected at random before isoniazid treatment was started by obtaining (1) an introspective statement by the patient estimating his own mood and state of well-being; (2) a clinical evaluation of his emotional state by a trained observer; (3) an evaluation of his mood and attitude by psychological testing; and (4) a pain threshold determination.

The psychological tests included the Guilford inventory, which "has been shown to be an adequate indication of the extent to which a person is depressed or cheerful, introverted or extroverted, happy-go-lucky or serious-minded, and flighty or stable," and 5 of the 80 sentences in the Madison Sentence Completion Form: (1) The future looks . . .; (2) The chances of my getting better . . . ; (3) Ten years from now . . .; (4) I feel I am getting . . .; and (5) The longer I remain in bed . . . After two or three weeks of treatment the four indexes of emotional status were reapplied. Neither consistent nor significant emotional changes were found, and none of the patients became euphoric. This confirms the later reports, suggests that the elation observed in earlier patients was a reflection of indirect psychological factors, and demonstrates again the need for objective testing and cautious interpretation of findings especially when observing the effects of a new drug.

SYNTHESIS OF PITUITARY HORMONES

Du Vigneaud and his associates working at Cornell University have announced the total synthesis of the oxytocic hormone of the neurohypophysis.[1] This achievement is particularly significant in that it represents the first reported synthesis of a polypeptide hormone. In a recent editorial in THE JOURNAL,[2] attention was drawn to the remarkable advances made by this group of workers in the purification and identification of the oxytocic and pressor hormones. They established that the oxytocic hormone consisted of one equivalent each of eight amino acids and three equivalents of ammonia, and on the basis of various physical properties and chemical reactivities of the highly purified natural hormone they deduced the probable chemical structure. Despite the extreme technical difficulties that beset work of this nature, they succeeded in synthetizing this compound, which has proved to be virtually identical with the natural oxytocin in regard to biological activity and chemical and physical properties.

In parallel studies,[3] du Vigneaud and his associates have postulated a structural formula for vasopressin that they had previously shown to differ from oxytocin in that leucine and isoleucine were replaced by phenylalanine and arginine or phenylalanine and lysine, depending on whether the active principle was isolated from beef or hog glands.[4] They have prepared an octapeptide with a structure corresponding to that proposed for lysine-vasopressin, and their preliminary studies indicate that this compound possesses both pressor and antidiuretic activity.

The natural corollary of these studies will be the synthesis of closely related compounds so that the effect of structural changes on biological properties can be studied, with the ultimate expectation that the limitations of the natural products in clinical use may be overcome. The fact that there is apparently a fundamental difference between vasopressin from hog and beef pituitary glands suggests that considerable modification of the molecule may exist without loss of biological activity. Furthermore, if this difference is confirmed, it will represent an interesting example of hormonal species difference that may account for the clinical observation that sensitivity to posterior pituitary injections is apparently occasionally overcome by switching to another commercial preparation.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

The end of an old year and the beginning of a new one is both a sad and a happy time. It is an occasion for reflection on what might have been and resolution to do better in the future. It is also a time for taking count of our blessings. We in American medicine have much to be thankful for, although as individuals we might have innumerable complaints. This fact was brought home to me once more as I attended the Board meetings and House sessions in St. Louis earlier this month and walked through the aisles of exhibits at Keil Auditorium. Here were assembled nearly 3,000 doctors who took time from their practices to seek additional scientific knowledge for the benefit of their patients. And these men were there because they *wanted* to attend the A. M. A. Clinical Meeting, not because someone had *decreed* that they should.

My only regret is that there were not more physicians at the session. There is much of scientific value to be gained at these clinical meetings, and the doctors of America are afforded a splendid opportunity to demonstrate the efficacy of free medical enterprise and their interest therein.

In addition to the purely scientific aspects of the St. Louis meeting, there were important actions by the A. M. A. House of Delegates on social security, voluntary health insurance, medical ethics, medical education, hospital accreditation, military affairs, and a wide variety of other subjects affecting both physicians and the public. A detailed account of these actions will be found in another section of THE JOURNAL. I hope that every physician who reads this page will make it his business to familiarize himself with the details.

That brings me right up to what would be the number one item on the list if I were asked to suggest some New Year's resolutions for doctors: "Know your local and state medical societies and their activities. Then make yourself just as thoroughly acquainted with the activities and the policies of the A. M. A."

It is a source of constant wonderment to me that so many physicians are so utterly devoid of knowledge of the policies of the A. M. A. and their local and state medical societies. And I dare say that only a minority of doctors could enumerate the many good acts of public service being performed by their medical organizations.

Make the test yourself sometime. Ask a fellow physician if he can tell you what connection the American Medical Education Foundation has with the A. M. A. and your county and state medical societies. Or have him explain to you the action that was taken by the A. M. A. House of Delegates in June of this year relative to medical care for war veterans.

Frankly, I am chagrined with statements that begin: "Why doesn't the A. M. A. do this . . .?" Or, "Why must the A. M. A. do that . . .?" Actually the A. M. A., as represented by the officials you elect or hire, cannot do anything until you have designated your desires in the meetings of your local or state medical societies. *You* are the A. M. A.

Surely this lack of knowledge of which I speak is not due to a shortage of information. There are scores of medical journals published by county and state medical societies and by the A. M. A. And from the national headquarters of your association there flows a steady stream of printed booklets, brochures, stuffers, newsletters, mimeographed correspondence, and individual replies to an endless chain of special queries. Besides the printed or written word, there are available tape recordings, motion pictures, and film reproductions of television shows that tell the story of organized medicine. Supplementing all of these sources of information are the speakers who travel the length and breadth of the land telling the story of American medicine's service in the public interest.

Maybe I am barking up the wrong tree, but the only answer I can find to the riddle of why there are so many uninformed doctors is that a successful method of communicating ideas to the individual physician has not yet been devised either by his local and state societies or by the A. M. A. No one has yet worked out a sure-fire system of getting the busy doctor to read his medical journals or to look at the mail from the medical groups to which he belongs.

I am hopeful that what I have written here may help stir up some ideas on how to solve this problem. But, until a solution is found, I beg some consideration for my humble suggestion that individual physicians resolve to make it their business to become acquainted with what organized medicine is doing not only for the general public but for the doctor as well.

It is my sincerest wish that the year 1954 will bring to you and every member of your family the blessings of happiness, good health, and a full measure of the good things that we all desire for our loved ones. Above all I pray that God shall bring to the world—and thus to our lasting benefit—a real and permanent peace.

EDWARD J. MCCORMICK, M.D.
Toledo, Ohio

ORGANIZATION SECTION

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE CLINICAL MEETING IN ST. LOUIS, DEC. 1-4, 1953

The actions of the House of Delegates at the St. Louis Meeting are herewith abstracted so that the readers may have this information in digest form. The official proceedings will be made available, as in the past, in a booklet, which will be sent to all members of the House of Delegates and officers of the American Medical Association by the Secretary. This booklet will not be available for several weeks.—ED.

Invocation

The Right Reverend Arthur C. Lichtenberger, Bishop of the Episcopal Diocese of Missouri, pronounced the following invocation:

Let us pray. Almighty God, who art the giver of light and health, who knowest how the sick have need of a physician, sanctify, we pray Thee, those whom Thou hast called to study and practice the art of healing and the prevention of disease and pain. Strengthen them in soul and body and grant that they may learn their art in dependence upon Thee, and practice it always under Thy sanction and to Thy glory. Strengthen them in body and soul. Give them wisdom and skill, sympathy and patience. And we pray, O Lord, that Thou wouldst govern in their deliberations these delegates here assembled with Thy purpose, illumine their minds with understanding and insight, that in all their decisions they may further Thy purpose for mankind. We ask it in the name of Jesus Christ, our Lord and Savior. Amen.

Preliminary Report of Reference Committee on Credentials

Dr. Walter E. Vest, Chairman, reported that 149 delegates had been seated and that there were a few others whose credentials were not in order but who would be seated later. The Speaker announced that a quorum was present.

Roll Call

The Speaker called the roll of the House, and 177 delegates were recorded as present.

General Practitioner of the Year

Dr. Dwight H. Murray, Chairman, Board of Trustees, presented the following announcement:

It is my pleasure to present the name of the general practitioner who has been selected for the annual award of the American Medical Association of General Practitioner of the Year. He is Dr. Joseph I. Greenwell of New Haven, Ky., 80-year-old active practitioner, who was born in Balltown, Ky., Nov. 27, 1873. He was educated in the Nelson County, Kentucky, public schools; at Cecilia College, from which he received his B.A. and M.A. degrees, and at the Louisville Hospital College of Medicine, from which he obtained his M.D. degree in 1900. For the last 53 years, Dr. Greenwell has practiced in Nelson, Hardin, LaRue, and Marion counties, mostly within a 25 mile radius of New Haven, where he has maintained his office throughout this period. He has been acting health officer for Nelson County for the last eight years and is a consulting physician for the Louisville and Nashville Railroad, and Gethsemane Abbey. During World War II he served four years as examining physician for the Nelson County *Selective Service Board.*

Perhaps the greatest source of professional pride for Dr. Greenwell has been the babies he has delivered, almost 4,300. Of these, more than 80 were born *this year. These deliveries* [illegible] ken place in everything from log cabins to the modern facilities of the new Flaget Memorial Hospital, Bardstown, which the doctor now uses almost exclusively.

Second only to the immediate welfare of his patients, Dr. Greenwell's greatest interest has been furtherance of the medical profession. He has been active at state, district, and county levels. Until his resignation this year, he served for 30 years as councillor for the fourth district of the Kentucky State Medical Association. He is a past president of the Nelson County and Muldraugh Hill Medical societies, and a member of the American, Kentucky State, and Southern medical associations. Dr. Greenwell has also been active in community affairs. He served 25 years as a member of the New Haven board of trustees and 14 years as mayor. Under his administration as mayor, townspeople saw the construction of New Haven's first sidewalks, the installation of street lights, and the erection of a public water works. He is a director and vice president of the Bank of New Haven. Dr. Greenwell and Miss Marie M. Rapier were united in marriage Nov. 25, 1903, and to this union were born 12 children. Eight are living. Two sons were lost during World War II, one being killed in action. Mrs. Greenwell died in May, 1950. The Board of Trustees is proud of a profession which can produce men of the caliber of Dr. Greenwell.

Adoption of Minutes of New York Annual Meeting

The minutes of the annual meeting held in New York, June 1 to 5, 1953, were adopted as printed and distributed to the members of the House of Delegates.

Report of Reference Committee on Rules and Order of Business

Dr. Joseph B. Copeland, Chairman, presented the following report, which was adopted:

Your Reference Committee on Rules and Order of Business recommends the following: (1) that the order of business be as published in the Handbook, with permission given to the Speaker to make any necessary adjustments unless there is objection from the House at that time; (2) that the Speaker, or, at his request, the President or the Chairman of the Board of Trustees, be granted permission to introduce to the House for an address persons who can give the members of the House pertinent or timely information; and (3) that the Speaker recess the House for lunch at a time to be determined by him.

Presentation of Medal to General Practitioner of the Year

Dr. Edward J. McCormick, President, presented the General Practitioner Gold Medal Award to Dr. Joseph I. Greenwell, New Haven, Ky., who accepted it with the following remarks:

Mr. Speaker, Members of the House of Delegates: I know that this house has many pressing and important matters before it, so I shall express my thanks for this great honor as briefly as possible. Needless to say, I am deeply moved by the honor that you have conferred on me.

We in Kentucky have always been proud of the fact that our state has provided the American Medical Association with more presidents than any other. Because of this, I feel especially honored to be the first Kentucky general practitioner to receive this award. While I am happy to have been singled out as the individual to receive this award, I cannot help but feel that in reality I am but a representative of Kentucky's medical profession. It has been my privilege to know well many of Kentucky's doctors and they are fine men devoted to service to their patients. There are many of them who are truly outstanding physicians. Today I am merely representing them. Again I want to thank you for this honor. It is the greatest in my life.

Remarks of the Speaker, Dr. James R. Reuling

The Speaker presented the following remarks, which were referred to the Reference Committee on Reports of Officers:

Members of the House of Delegates of the American Medical Association:

That there is much serious work for this and subsequent houses to do, there can be no doubt. In the opinion of your Speaker, things are not going too well. He believes times are just as troubled as they were when we had blanket bills before Congress which would have socialized the practice of medicine. There is a war of attrition going on. The socializers are not dead. They are still at work but taking little bites, nibbles here and nibbles there; we must all be alert to the change in tactics. There were over 259 bills introduced into the last Congress dealing with medicine and health, or having welfare implications affecting medicine, and from all indications this number will be exceeded in the coming session.

To touch on some of the problems that confront American medicine today and to mention only a few, we have nonservice-connected disability; dependent medical care; government subsidy in many, many fields—to education, both premedical and medical; government subsidy to hospitals; proposed government subsidy to students; Veterans Administration medical education and training progress; health and welfare agencies galore; the doctor draft; state aid; and civilian medical care.

Listen to reports carefully. You would all be surprised and astounded if you knew the hours of work and conferences, the study, the research and writing that go into the reports which are presented to you; the miles the President, the President-Elect, and the Trustees travel, as well as some of the members of this House and numerous members of the Association who serve on councils, bureaus, and committees.

You always do give reports careful attention, for as this speaker has said many times before, he has the greatest respect for the combined judgment of this body. You always come up with the right answers, which proves that you listen carefully. But now more than ever, it is necessary for you to listen, digest, and assimilate even more carefully than usual, for each and every one of you must be a missionary. When all of the reports have been heard and you have voted on the last proposition before this House is adjourned, your work as a delegate is not done. Your labors really at that point have only just begun, for, if we are to be effective, each and every one of us must be a missionary in our own community and in our own state to carry back to the grass roots the story, the problems, and the possible solutions to the problems, not only in improving the health and care of our citizens but also to protect them from the "well-doers." If the socializers are to be stopped, if we are to prevent bureaucratic control in Washington from making inroads into our lives and the lives of all of our citizens, if we are to keep medicine from being fettered, the responsibility lies on each and every one of us.

For years after this country was founded, one of the elements which made it strong was the habit of mutual assistance—neighbors giving aid to those less fortunate, community responsibility, not bureaucratic control, and aid at the local level, not someone at the top giving orders. The doctor at the local level has always been a key figure in community responsibility. The Fabian doctrine says control medicine and you can socialize everything else. There are a few in the profession who say "Why doesn't the county medical society or the state medical society or the American Medical Association do something about it?" That individual is very apt to be one who has lost his own personal sense of individual responsibility.

We have standing rules of the House that are procedural matters that should not be in the Bylaws. Your Speaker recommends that the House consider and adopt a standing rule of procedure that resolutions be in the hands of the secretary at least 48 hours prior to the meeting of the House. If such a rule is adopted, the exceptions presented in the Bylaws, that is, those originating in sections and those relating to business of an urgent nature, would still prevail. What would be the purpose of such a standing rule? There are several that are quite obvious that I have touched on in a letter sent to each of you recently.

1. It will give an opportunity to study the material and make more accurate references. 2. Resolutions can be numbered serially so that all of the delegates can identify them readily. 3. The resolutions can be published "by titles only" in the Daily Bulletin together with the names of the reference committees to which they are assigned. This will not only give the delegates accurate information, but members of the Association at the meeting will have an opportunity to appear before a reference committee in matters in which they are interested. 4. If resolutions have any implications that might lead to bad public relations or unfavorable press relations, such stigma can be eliminated or reduced by having the opportunity of discussing the resolution in advance of introduction. 5. The resolutions can be multigraphed in advance at headquarters, thereby taking much of the load off our small office staff at the time of the session. I would recommend that the reference committee give this matter serious consideration so that we may minimize such baseless and absurd articles as appeared after our last meeting under the title "Watch It Doc."

At the last meeting, there was unfortunate wording in a resolution introduced. The intent would have been clear to a first year high school student. The unfortunate wording would have been picked up had we had time to see the resolution in advance, and finally the action of the House could not possibly have had any such interpretation as appeared in the press. It occurred only because a copy of that resolution was left lying around and was picked up before the reference committee met, before any hearing had been held, before the reference committee wrote its report, and before the House had taken any action.

At this point, your attention is called to the mimeographed copies of resolutions that have been made in order to make your work easier. This was a new procedure at the last meeting, and I want to emphasize and stress a point which might be overlooked. The copies of these resolutions should be considered "confidential material." No copies are to be given to anyone. They should be confidential because until they are introduced and referred and until the reference committee has had hearings and has drawn up its report and finally until the House has voted on that report, all resolutions are quite rightly the opinion of the introducer or a small segment of the profession. Resolutions introduced do not constitute any action, opinion, or policy of the American Medical Association. To let your copies lie around loose where they might be picked up by someone prior to action having been taken would, to say the least, be a violation of good taste.

Your speaker would call attention to the necessity of your signing attendance slips each day for sessions of the House. These are necessary for several reasons: first, for the proper records at headquarters; secondly, that due credit be given for your presence in the published report of the proceedings; and finally there are some state associations that require attendance at all sessions in order that their delegates may be reimbursed for their expenses.

There are two reference committees which seldom have a large volume of material referred for their consideration: The Reference Committee on Hygiene and Public Health, "to which shall be referred all matters relating to hygiene and public health," and the Reference Committee on Industrial Health, "to which shall be referred all matters relating to workmen's compensation and those phases of medical care, including rehabilitation and public health administration, which affect the worker." It is your Speaker's opinion that these might well be combined into one reference committee and it is so recommended.

There are times when the Reference Committee on Miscellaneous Business is literally snowed under. The suggestion is made that we have two such committees, Miscellaneous Business A and Miscellaneous Business B, to which shall be referred alternately all other business not allocated to any of the enumerated committees or additional committees appointed pursuant to chapter XII, section 1, of the Bylaws. This is only a suggestion, and your speaker would recommend that the suggestion be referred to the Council on Constitution and Bylaws with such comment as the Reference Committee on Reports of Officers may wish to make.

The suggestion has been made by several that we have blackboards set up in each reference committee meeting room and that the chairman of each committee list thereon the material that his committee will hear and act on and also the hour at which each resolution will be heard. The suggestions are excellent except for one thing—time. It is the belief of your speaker that the publication in the Daily Bulletin may care for a part of this suggestion. However, the listing of the time at which a reference committee will hear a certain resolution is not realistic. If any of the chairmen at this meeting are able to do it, more power to them. If the committee to whom this report is referred can come up with any ideas or suggestions, fine. Your Speaker has been a member and has been chairman of reference committees. Time after time things that seemed controversial and might take two hours have been settled in five minutes. Contrariwise, a resolution that appeared on the surface to be perfectly innocuous had innumerable individuals who wanted to be heard and has taken hours to settle.

Report of Reference Committee on Reports of Officers

Dr. George M. Fister, Chairman, presented the following report, which was adopted:

Speaker James R. Reuling began his address at the Clinical Meeting on Dec. 1, 1953, with the timely warning that the struggle against socialization and compulsion of American medicine had not diminished. Methods and tactics have changed and we must be alert. He enumerated many of the problems confronting us. Your committee wishes to emphasize the wisdom of his suggestion that when meetings are completed, the work of a delegate has only begun. It is the missionary duty of a delegate to take back to, and discuss with, his colleagues the problems presented to the House and the conclusions reached for their solution. In order to implement this recommendation, your committee suggests that a résumé of the proceedings of the House be distributed by state or county societies to all members of the American Medical Association under their jurisdiction.

Speaker Reuling suggested important changes in procedure with a view to facilitating the business of the House. He recommended that, as nearly as possible, resolutions be in the possession of the Secretary 48 hours prior to the first meeting of the House. Your committee favors the adoption of this recommendation in the belief that such a procedure will disseminate information regarding resolutions and permit mimeographing, numbering, and leisure study. It is understood, however, that, as in the past, resolutions may be presented during sessions of the House. Your committee recommends that mimeographed, numbered copies of all resolutions be made available to delegates and that delegates consider the contents of resolutions confidential until the House has disposed of them. The Speaker called attention to the advisability of signing attendance slips. This is necessary in order that proper records may be compiled.

It was recommended that the Reference Committee on Hygiene and Public Health and the Reference Committee on Industrial Health be merged into one committee. Your committee approves this recommendation in principle, but believes it is a matter for action by the House.

Speaker Reuling requested opinions as to procedure in appearing at meetings of reference committees. It is suggested by your reference committee that members desiring to discuss certain subjects contact the chairmen of the reference committees involved and arrange a definite time for their appearance.

Reference Committees, Tellers, and Sergeants-at-Arms

Dr. James R. Reuling, Speaker, announced the appointment of Reference Committees, Tellers, and Sergeants-at-Arms, as follows:

Amendments to the Constitution and Bylaws

William L. Benedict, *Chairman,* Section on Ophthalmology
Frank J. Elias, Minnesota
Charles L. Farrell, Rhode Island
William M. Skipp, Ohio
Deering G. Smith, New Hampshire

Board of Trustees and Secretary, Reports of

John J. Masterson, *Chairman,* New York
James Q. Graves, Louisiana
Gordon F. Harkness, Section on Laryngology, Otology, and Rhinology
L. Howard Schriver, Ohio
Norman A. Welch, Massachusetts

Credentials

Walter E. Vest, *Chairman,* West Virginia
Vincent W. Archer, Virginia
Thomas M. D'Angelo, New York
Harlan English, Illinois
James P. Hammond, Vermont

Executive Session

Joseph D. McCarthy, *Chairman,* Nebraska
Reuben B. Chrisman Jr., Florida
Lawrence R. Dame, Massachusetts
John S. DeTar, Michigan
Peter M. Murray, New York

Hygiene and Public Health

Thurman B. Givan, *Chairman,* New York
Jay J. Crane, Section on Urology
William L. Estes Jr., Pennsylvania
Hoyt B. Woolley, Idaho
Stanley B. Weld, Connecticut

Industrial Health

Frank A. MacDonald, *Chairman,* California
William R. Brooksher, Arkansas
James Stevenson, Oklahoma
William Weston Jr., South Carolina
Dexter H. Witte, Wisconsin

Insurance and Medical Service

John M. Porter, *Chairman,* Kansas
Eustace A. Allen, Georgia
Henry S. Ruth, Section on Anesthesiology
Robert B. Wood, Tennessee
Willard A. Wright, North Dakota

Legislation and Public Relations

Bruce Underwood, *Chairman,* Kentucky
R. B. Homan Jr., Texas
J. Stanley Kenney, New York
H. Kenneth Scatliff, Illinois
C. F. Strosnider, North Carolina

Medical Education and Hospitals

James Z. Appel, *Chairman,* Pennsylvania
Warde B. Allan, Maryland
Warren W. Furey, Illinois
Charles T. Stone Sr., Section on Internal Medicine
Lewis A. Alesen, California

Medical Military Affairs

William A. Hyland, *Chairman,* Michigan
H. Russell Brown, South Dakota
Donald C. Conzett, Iowa
J. Lafe Ludwig, California
Wendell C. Stover, Indiana

Miscellaneous Business

H. Gordon MacLean, *Chairman*, California
J. Wallace Hurff, New Jersey
Harold B. Gardner, Pennsylvania
Truman C. Terrell, Texas
Martyn A. Vickers, Maine

Reports of Officers

George M. Fister, *Chairman*, Utah
Maurice J. Dattelbaum, New York
J. Paul Jones, Alabama
William H. Halley, Colorado
George A. Woodhouse, Ohio

Rules and Order of Business

Joseph B. Copeland, *Chairman*, Texas
Herbert H. Bauckus, New York
William W. Baum, Oregon
Edward L. Compere, Section on Orthopedic Surgery
O. J. Campbell, Minnesota

Sections and Section Work

Jesse D. Hamer, *Chairman*, Arizona
W. Andrew Bunten, Wyoming
Raymond F. Peterson, Montana
J. Mather Pfeiffenberger, Illinois
Alvia G. Young, Washington

Tellers

Carrington Williams Sr., *Chairman*, Virginia
William F. Brennan, Pennsylvania
Raymond T. Holden, District of Columbia
Wesley W. Hall, Nevada
Rolla B. Wray, Missouri

Sergeants-at-Arms

Louis W. Jones, *Master Sergeant*, Pennsylvania
John F. Lucas, Mississippi
Karl R. Ruddell, Indiana

Address of the President, Dr. Edward J. McCormick

Dr. Edward J. McCormick, President, presented the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

During the meeting of the House of Delegates in New York in June, 1953, I brought to your attention certain activities and problems of American Medicine. I mentioned the distribution of doctors, the 24-hour emergency call service offered by more than 600 county medical societies, and the necessity of fearless grievance and mediation committees in each county and state society. I spoke to you of physician-hospital relationships and of the necessity for continued expansion of voluntary health insurance plans. I encouraged physicians to take part as leaders in the activities of service clubs, fraternal associations, parent-teacher groups, church associations, and others. I made reference to our relationship with the representatives of the press, radio, and television. I asked for unity within the profession.

Since the June meeting of the American Medical Association, countless hours have been spent on planes and trains and in meetings, and I come now to give you the impressions gained during these weeks and months as your President and spokesman.

I am happy to report that progress has been made in the development and implementation of the nine major points which I brought to your attention in New York in June, 1953. However, I would be derelict in my duty and unfaithful to the oath of my office if I did not point out some of our failures.

You cannot have an understanding of medicine's problems unless you meet the press, the people and patients, doctors, and industrialists, and executives on a wide base of transcontinental travel and multiplicity of contacts at all levels. I once believed that after all my years of experience in medical circles at county, state, and national levels, I was well-qualified for the honor which you bestowed on me. However, I soon discovered, and I presume so did many who came into this high office before me, that I had much to learn despite all of my previous experience. And what have I learned in the past six months that would be of interest to this House of Delegates?

First and uppermost is the fact that our relations with the public are not good. Since the Oath of Hippocrates was written, five centuries before Christ, there have been fewer "crooks" in medicine than in any other group with the exception of the ministry, and I say this without reservation or qualification! Yet, as I make this statement, I feel that it is necessary for you, as representatives of your state medical associations, to return to your home and campaign for stronger grievance committees and the expulsion of those who disregard the Principles of Medical Ethics.

Please understand that I am diametrically opposed to a program of national publicity emphasizing the defects of a small number of doctors and heaping on the great percentage of honest physicians and surgeons, who work 12 to 18 hours a day, the sins of a few. But we cannot close our minds to the need for some action that would restore the full confidence of the public in our profession. I have come to the conclusion that bad public relations is a "grass roots" problem and cannot be solved at the national level. Good public opinion cannot be bought. It must be earned through exemplary conduct and genuine service in the public interest. Whatever money the American Medical Association and its constituent societies spend for public education and public relations is wasted unless individual physicians take wholehearted interest in assuring the success of these ventures.

Doctors must know more of public thinking regarding fees and physician-patient relationship if we are to continue to exist as free scientists and practitioners. The thousands of letters which I have received and which come to the headquarters office, plus derogatory articles in the press and magazines, leave little room for argument. We have a policing job to do, and it must be done through the medium of existing disciplinary machinery. It cannot be done in any other way.

The great growth of voluntary health and hospital insurance plans and the advent of catastrophic coverage, the unprecedented accomplishments of the past 25 years, the great increase in longevity, the excellent work of our various councils and committees in the American Medical Association are easily forgotten, but not so unethical practices of any kind. True, some of our critics are unfair, explaining only that which is bad and giving no credit for positive accomplishments. And some, I find, are not even sympathetic to American fundamentals. As citizens and doctors we must not give them a target to shoot at. No group of humans can be perfect, but we can seek perfection in the discharge of our humanitarian duties—and in seeking perfection we shall find good public relations! There is no other answer.

In the past six months I have also learned that our economic problems are not solved, as some physicians seem to believe. As a matter of fact, these problems have increased. The socialistic trend and government intrusion into the business and affairs of the people have shown little evidence of change. The greatest battle for the preservation of democracy is yet to come. I see it in the demands of some labor unions and in the desires of certain professional veterans to continue unabated the ever-increasing government support of more than 20 million veterans. I see it in the drafting of doctors for an ever-growing dependent care program, as well as in proposals from federal sources that the government buy hospital and medical care insurance for members of the armed forces and their families. I recognize it in the long list of diseases presumed to be service-connected. It appears in the statements of elected public officials who believe that it is "good politics" to encourage federal handouts of all kinds and who, by innuendo and by word, magnify the medical needs of our people and pay little heed to the many more important problems affecting American men and women.

If America is to survive as a democracy, in which man is recognized as having been created "in the image and likeness of God," possessed of a soul, and having certain inalienable rights and privileges, then we, as doctors and leaders, must request that all other groups, including writers, journalists, union leaders, and industrialists adopt a similar code of ethics, or, if they have such a code, make it just as operative as they expect the medical code of ethics to be. Our friends and fellow citizens in other vocations, including public officials, must conduct their affairs with the same dignity and integrity manifested by the great majority of physicians. If we police our own ranks, as we have tried to do for centuries, they should do likewise.

Finally, It would seem to me that, since medicine in America is the best in the world and improving every day, orators, writers, and others might do well to devote more of their attention to far greater problems affecting the health and welfare of the people, such as housing, sanitation, juvenile delinquency, nutrition, un-Americanism in many of our institutions, dishonesty of public officials, gambling, gangsterism, and other cancers on our national economy, including the collectivists and socialists and communists, and those who, having lost sight of God, have forgotten that we are a great nation because of a Constitution written by men with a deep faith in the Supreme Being, faith in opportunity, and in private enterprise.

The councils and committees of the American Medical Association have done and are doing magnificent work in the field of public service. I know of no other organization which spends so much time and money in altruistic purposes. It seems, however, that many doctors and most laymen know little of the unselfish accomplishments of medical organizations. It would seem that newer techniques should be developed to carry to physicians and others the problems which daily confront your officers, Board of Trustees, and councils and committees. I make this statement because I am convinced that the great percentage of our membership, while acquainted with our scientific endeavors, are devoid of knowledge of the hours of work and travel given without remuneration by the elected officials of the American Medical Association family and members of this House of Delegates. I should like to see this information carried into every doctor's home—short, concise, and readable.

For example, I dare say that there are many physicians in St. Louis today who have no knowledge of the work and decisions of our Committee on Legislation. How can they be forceful in discussing these problems? How can they be encouraged to read the Organization Section of The Journal? Is there a better way of bringing greater understanding of medicoeconomic problems into the doctor's living room? Can a better method be designed to bring medical problems to the busy doctors? I submit these questions to this House of Delegates and to our state executives and county societies in good faith, with the firm conviction that, despite our efforts and hard work, unwarranted criticism comes from many sources due to lack of knowledge on the part of some physicians and laymen of our aims and purposes.

There are many other subjects that I might discuss, but time will not permit. I should like to suggest to this House of Delegates and to our Council on Medical Education and Hospitals that the time has come when we should insist that a reasonable amount of time be devoted by our medical school faculties to the formal teaching of medical ethics and the religious fundamentals which are just as evident in the Oath of Hippocrates and the Principles of Medical Ethics as they are in the Constitution of the United States of America. Here again is a job for the "grass roots," in this case the medical schools. On them must rest the responsibility of graduating men and women of character who will be immune to socialism and communism as well as unethical practices in medicine. It is comparatively simple to train a person to be upright and honest, but it is difficult to convert such a person when he or she has strayed from the path of honor and brought reproach on the world's most honorable profession.

When one becomes President of the American Medical ssociation, he has received medicine's greatest honor! He ise has assumed a position which is rapidly becoming a full-time responsibility. Permit me to admit that without the excellent staff provided at the headquarters office I would be unable to carry on. Every council and committee, each and every department head has rushed to my rescue on many occasions! We have as fine and capable a group laboring for us day and night in Chicago and in Washington as has ever been assembled by any major organization. To them one and all, my gratitude and thanks.

To you, my colleagues of this House of Delegates, I wish to restate my earnest pledge to carry your thinking throughout our great country. I hope that six months from now, after having completed the mission to which I have dedicated myself, I can find peace of soul and heart because of few, if any, errors of omission or commission. This goal I shall be able to achieve only with your help and support. Let us all resolve here and now to carry on in our efforts to bring the best medical care to all the people in our native land and to oppose each and every suggestion which directly or indirectly would seem to jeopardize our great democracy.

Report of Reference Committee on Reports of Officers

Dr. George M. Fister, Chairman, submitted the following report, which was adopted:

Your committee received for consideration the address of President Edward J. McCormick. At the Clinical Meeting on Dec. 1, 1953, and in a brilliant and factual manner, President McCormick reviewed the first six months of his stewardship, and indicated the arduous road that our profession must travel with increasing vigilance and unity if our objectives are to be realized and our ambitions brought to fruition. In his New York address in June, 1953, President McCormick recommended nine major activities to the accomplishment of which he has directed his energies. It is gratifying to have him state that progress has been made. Your committee believes that this statement is too modest. Our relations with the public must and shall be improved. President McCormick points the way. Your committee believes, with him, that public relations is a "grass roots" problem, and interprets "grass roots" to mean every physician in his every contact with every patient every day. This is fundamental.

A committee, on state or county level, to hear and evaluate complaints and criticisms is of value in direct ratio with the courage of its personnel. The legal concept that the greatest deterrent to crime is the certainty of punishment should enhance the value of such committees.

We, as a profession, are subjected to much unfair criticism from the public and, regrettably, from some of our colleagues. Of our unethical and critical colleagues we may paraphrase and say, "Never before have so few done so much harm to so many." President McCormick suggests the remedy. He advises that "we seek perfection in the discharge of our humanitarian duties" and that we demand integrity and intellectual honesty in our critics.

If we are to acquaint the public with our real objectives and accomplishments, we must educate ourselves. President McCormick suggests that all physicians read the Organizational Section of The Journal and that the Principles of Medical Ethics be taught in medical colleges. Your committee congratulates President McCormick on his courageous attitude regarding government intrusion into what should be the private affairs of our people. Attention is called particularly to the arduous duties of the Presidential office, and to its physical, mental, and professional sacrifices.

Your committee suggests that this splendid address be disseminated as widely as possible through all channels of publicity.

Presentation of Drs. Julian P. Price and Carl H. Gellenthien

The Speaker presented to the House of Delegates for recognition Dr. Julian P. Price, Florence, S. C., Trustee, and Dr. Carl H. Gellenthien, Valmora, N. Mex., Vice President, who had been elected to their respective offices at the New York meeting but who, in the rush preceding adjournment, had not been introduced to the House.

Presentation and Address of Dr. Chester S. Keefer

Dr. Edward J. McCormick, President, was granted the privilege of the floor for the introduction of Dr. Chester S. Keefer, Special Assistant to the Secretary of the United States Department of Health, Education, and Welfare. Dr. Keefer addressed the House as follows:

Dr. McCormick, Mr. Speaker, Members of the House, Fellow Members: I wish to thank your president for inviting me to come here this morning and for the opportunity of addressing you. In June, 1953, Mrs. Hobby, the Secretary of the Department of Health, Education, and Welfare, addressed the House of Delegates and outlined the responsibilities of the Department in the areas of health. She defined the responsibilities as those functions which serve the health of the nation without affecting the doctor-patient relationship in medical practice. The Secretary directed attention to the department's activity in public health, in research and rehabilitation. These are matters that this Association has been concerned with for many years, because you have an intelligent grasp of their significance in the conservation of the human resources of the nation. Mrs. Hobby also stated that the common objective of the department and of the medical profession was to promote the best medical care and the highest level of health possible for the people. The means of reaching these goals raise many of the current problems, but I submit that with the leadership of this Association and the other health professions solutions can and will be found that will receive public acceptance. In the past, this Association has taken positive action with respect to advocating measures which are clearly in the public interest and general welfare, so that the people are justified now in looking to you for such leadership in the future.

The medical care of today is quite different from 25 years ago, and I am inclined to believe that you will agree that its present high quality is due to the principles that this Association has insisted on in the past, namely to advance the boundaries of medical knowledge, to elevate the standards of education, and to base the practice of our art on scientific principles and sound experience. It is proper therefore that the Association should continue to support scientific research, to examine the standards of medical education, and to further its development. This is the foundation on which the high quality of medical care rests. It is the function of the Association to utter the voice of medical science to the public concerning the significance and importance of research and medical education in the health problems of our country today.

I need not remind you that this Association has been responsible in large part for elevating the standards of medical education in the United States. This has been accomplished in the past by insisting on high standards, by approving or disapproving the performance of schools, and by informing the public of your ideals and objectives. This has been successful because the standards have been related to quality.

There are at least four agencies that are responsible for high quality of medical care and for the promotion and maintenance of the good health of the people. They are the medical schools, the hospitals and their staffs, the public health departments, the medical and other health professions.

First let me say a few words about the medical schools. The American Medical Association has had a continuing interest in medical education. The standards of such education are under constant examination by the Council on Medical Education and Hospitals, and periodic national surveys have been made and sponsored by your organization with the support of others. The most recent survey by the Committee on Survey of Medical Education has been reported in a book entitled "Medical Schools in the United States at Mid-Century." This study shows what progress has been made in medical education in the United States since 1910, but one also gathers from these reports that there are many problems that need urgent attention because there are danger signals ahead. When a patient is placed on the "danger list" by the physician it is putting the family, the friends, and the public on notice. The outlook is uncertain, and the patient may die. Bold action, soundly conceived, will be necessary if the standards of our medical schools are to be maintained and if they are to continue to meet their mounting responsibilities. Increased financial support from the public is urgently needed to meet the rising deficits. This is a challenge that must be met. The attitude of physicians should be clear in the matter of education, for the strength and credit of the profession, the great interest of the public health, and the welfare of the individual all depend on the quality of training given in our medical schools. The medical schools need the full support of the profession and of the public. The people need to be informed that they have a vital stake in the quality of medical care, and that is determined in large part by the education of our doctors and other members of the health professions. The medical schools of this country are almost equally divided between two types; the tax-supported, and the non-tax-supported. This has proved to be a healthy balance. However, the greatly increased financial burden which weighs equally upon all is jeopardizing particularly the future of the private institutions without large financial resources. The American Medical Education Foundation and the National Fund for Medical Education are making valiant and praiseworthy efforts to meet the increased costs of medical education within the framework of our private enterprise system and without resort to Federal assistance. May their efforts prosper, for this is not a time when this country can afford to cut down on its production of medical manpower.

Aside from the education of the members of the health professions, it is necessary that adequate facilities be available in the community so that doctors may utilize their skills and apply new scientific knowledge in the prevention and treatment of illness. Of great importance are the hospitals of the nation because these facilities and their staffs play an important role in providing essential health services to the committee that they serve. The public should be informed that equal opportunity for medical care is concerned with community facilities as well as adequately trained personnel. When facilities increase and improve and when well-educated physicians are trained, then the quality of medical care improves. This statement does not imply that the facilities need be the same in all areas. They must be adapted to the region and they must be selected in accordance with need. *This is a matter for each local community to decide for itself.*

The third agency that plays an important part in our health team are the health officers and their departments. They serve, educate, and protect the community against the hazards of illness. They assist the practicing physician in carrying out his mission and in safeguarding the public health. Their education, their development, and their opportunities are important to all of us.

The fourth agency that holds the major responsibility for promoting and maintaining the health of the nation is the medical profession. The profession must be the leader, and to reach their full potential requires the cooperation and the coordination of activities of the other health professions, including dentists, nurses, pharmacists, and the many groups of paramedical and technical workers. In short, the health of the nation is promoted by a team, and the medical profession must be the leader of the entire group. For this team to be most effective there must be good personal relations and understanding between the organized professions and the people whom they serve. The so-called doctor-patient relationship which we all prize so highly and which is the basis for the present day medical practice must extend to group relations, that is to say, the relations between the organized health professions and the people must be carried on with the same depth of understanding as the relationship between the individual doctor and his patient. One of the best ways of accomplishing good group relationships is for the profession to understand fully the needs of the people and for the profession to place themselves in the position of the patient.

The total problems of medical care will continue to require constant study. The problems are very broad, and include medical education, medical research, hospitals and their staffs, public health departments, the professions, and the people. The major question before us is how can we continue to produce and promote the finest medical care in the world today. Our needs are for improved medical education; for coordination and extension of facilities and personnel; geographical extension of services; and bringing the cost within the reach of more people. These needs will be met in our free society by the combined efforts of the laymen, and the members of the health professions working closely together with a sympathetic understanding in their local communities. The voluntary way has been most successful in the past and there are reasons to believe that it will continue in the future. We need experimentation in the field of medical care in order to find the answers to many problems. Experimentation should be carried out by the profession with the full cooperation of the people of the community and the maximum decision should be made at the local community level.

In 1910 the American Medical Association held its 61st annual meeting here in St. Louis. Dr. William H. Welch was President, and he selected for his Presidential Address the title, "The Fields of Usefulness of the American Medical Association." The final two paragraphs of his speech were devoted to the topic of "organized effort." They are as applicable today as they were 43 years ago, so with your permission I am going to conclude by reading them.

"Organized effort is a distinguishing mark of modern civilization. It is as essential for the advancement of science, of education, of social and industrial reform, of philanthropic endeavor, as for the promotion of commerce. With the remarkable progress of medical science, especially during the last three decades, man's power to control disease has been vastly increased, and the sphere of usefulness of the physician has been correspondingly widened, and with advancing knowledge will continue to expand. The skill and knowledge of the physician and sanitarian have acquired a new and ever increasing importance and significance in the movements for social amelioration, for improvement of the conditions of labor and of living, for the conservation and most efficient utilization of the productive energy of the world, and for the reclamation of regions now yielding no return to civilization.

"Among the organized forces for advancing the prosperity, the happiness and the well being of the people of this country, the American Medical Association has an important part to play. We are justified in the confidence that, with the united support and loyalty of the profession, the association, broadly representative and standing for the best ideals of medical science and art and for professional and civic righteousness, will contribute a beneficient share to the working out of our national destiny."

Introduction and Address of President of American Dental Association

The Speaker introduced Dr. Leslie M. Fitzgerald, President of the American Dental Association, who addressed the House as follows:

Dr. McCormick, Mr. Speaker, Trustees, Members of the House of Delegates of the American Medical Association: It is a great privilege for me to be here today to represent the officers and trustees of the American Dental Association.

I thought it might be of a little interest to some of you to know a few of the facts of our organization. Many of you know them, possibly some of you do not. The American Dental Association has a membership of approximately 80,000. We take great pride in the fact of such a large percentage of the practicing dentists being members of the American Dental Association. Eight out of every nine practicing dentists in the United States are members of the American Dental Association. Our organization is very similar to yours, operating under a house of delegates and a board of trustees.

The American Medical Association and the American Dental Association represent the two major health professional organizations and therefore share many responsibilities, such as improvement of the health of the public by the prevention and control of disease, advancement of the art and science of medicine, constant vigilance against political encroachment on the health profession services to the public, and improvement of public relations.

At this time, I would like to mention briefly one field in which the two professions have shown spectacularly close cooperation. I am referring to the fluoridation of the public water supplies, one of the greatest advances in the history of preventive dentistry. The story of fluoridation is a stirring tribute to research. The program is now in operation in over 800 communities and one out of every nine persons in the United States is routinely drinking fluoridated water. Local medical and dental societies have taken an active role in encouraging this measure. The cooperation of the medical and dental professions on this measure seems to me to be a graphic example of the health professions living up to their highest responsibility, the prevention and control of disease.

The united efforts of the American Medical Associatior and the American Dental Association also have done much t defeat unsound and ruinous legislation at both the nationa and local level. The American Dental Association House o Delegates, at its annual meeting in Cleveland last Septembe again reaffirmed its opposition to the inclusion of dentists i the O. A. S. I. program. The vote was 6 to 1. The America Dental Association has consistently voiced its opposition t all forms of compulsory health insurance. It is on record favoring the proposed Jenkins-Keogh Bill.

In conclusion, I wish to state that unity and cooperatic of our organizations are basic. If the present high level health care is to be protected, constant vigilance must maintained against political encroachment on the health pr fession services to the public. When politics takes over, tl welfare of the individual patient becomes a secondary co sideration. The American Dental Association pledges its co tinued support of sound legislation for the advancement the art and science of medicine and for the betterment of tl health care of our nation. The great prestige of the heal professions rests firmly on a solid basis of organized strengt This the American Medical Association and the Americ Dental Association should preserve.

Introduction and Address of President of Woman's Auxilia

Mrs. Leo J. Schaefer, President of the Woman's Auxilia to the American Medical Association, was introduced by t Speaker, and presented the following address:

Mr. Speaker, Dr. McCormick, Dr. Martin, Board of Tr tees, and Members of the House of Delegates: I am ve pleased to have this opportunity to report to you on the pr ress of the Auxiliary and to bring greetings from the 64,0 members. Within the 48 state auxiliaries, the District Columbia, and the territories of Hawaii and Alaska, we ha more than 1,130 county auxiliaries. We are fully cogniz of the fact that we are an auxiliary to our parent organi tion, the American Medical Association, and as such und take projects approved by our Advisory Committee, wh will assist the medical profession in its program for the vancement of medicine and public health.

In reading the papers, the magazines, listening to the rac and watching TV, we are aware that people do want to kn about subjects relating to health. The Auxiliary, through state and county units, can make an important contribut to the community when it interprets the problems of medi care to the public. Programs for our Auxiliary meetings m be planned to inform our members on problems facing medical profession and ways in which physicians are solv them. As Auxiliary members we have a two fold service render, (1) education of ourselves in subjects relative to medical profession and (2) bringing this message of medic to our home communities through the organizations in wh we hold membership. There was a time not too many ye ago when it was not necessary for a physician's wife to informed concerning health problems that affect the pub but today she must be informed or offer no comments.

Members of the House of Delegates, we need your h The American Medical Association reports a membership 140,000. At the close of our June fiscal year we had 64, members. Our organization chairman is asking for a 1 increase in membership this year, but with your help we co double our membership. The present membership is carry the full program for the Auxiliary. The nurse recruitm program, with its scholarships, loan funds, and Future Nu Clubs in high schools is outstanding. No doubt you h heard of our contribution to the American Medical Educat Foundation fund. Last June for the third consecutive year gave $10,000 from our income. In addition the state auxilia contributed $22,630, and in June, 1954, we are positive amount will be doubled. We also take a little credit for the increased contributions from our physicians. We contribute annually $100 to the World Medical Association. Our only source of income is from our $1.00 annual dues per member. A membership paralleling that of the American Medical Association would increase our philanthropic projects. We are aware that *Today's Health* is an excellent medium for distributing authentic health information. People eagerly read medical articles in other magazines, so why not make authentic information available to these readers? Our goal this year is 64,000 subscriptions, or one subscription per member, which is double the subscriptions of last year. Since only 15% of the physicians subscribe to *Today's Health*, with your help we can reach our goal.

Other programs of the Auxiliary do not have such tangible records; their value cannot be estimated in dollars or numbers. We aim to be informed on legislation affecting medicine; we assist with the civil defense program; we inform ourselves concerning mental health, rural health, health days, voluntary health insurance, community health councils, the American Medical Association; the World Medical Association; the World Health Organization; and other health projects such as cancer, polio, and heart.

The conference of state presidents, presidents-elect, national chairmen, and officers held in Chicago last week was attended by representatives from all 48 states. We are grateful for the valuable assistance rendered by representatives from several departments of the American Medical Association and for the excellent address by your president, Dr. McCormick. Each member returned home more eager than ever to assist their state and county medical societies in any program assigned to them.

It has been my pleasure to attend 13 state auxiliary conventions, 4 state board meetings, and 5 other national meetings since June and to witness first hand the fine programs being developed. The Woman's Auxiliary to the American Medical Association truly exemplifies the slogan of this year "Together We Progress." May I add, with your continued help "Together We Can Progress" more rapidly. I thank you for this opportunity to be with you today.

Introduction of Student A. M. A. Delegates

The Speaker introduced Mr. John H. Caskey, Baylor University College of Medicine, and Mr. David J. LaFond, Marquette University School of Medicine, delegates from the Student American Medical Association, who presented greetings from their organization.

Presentation and Remarks of Rev. Alphonse M. Schwitalla, S.J.

Rev. Alphonse M. Schwitalla, S.J., of St. Louis, was presented by the Speaker, and addressed the House as follows:

Being a Jesuit priest precludes any possibility of my ever attending a conclave of the Cardinals for the election of a Pope, so my next ambition has been, before I die and make a report to the "Big Boss," at least to have once appeared before the House of Delegates of the American Medical Association.

The American Medical Association is composed of a group of sound thinkers, and in the work that I have done I have felt that whenever I have made a false step, it was always because I had done something that was contrary to what the American Medical Association has taught. Fortunately, I have had friends like Ed McCormick and Herman Weiskotten and Dr. Cutter and a few other people who have acted as intermediaries between you and me.

Just yesterday I was reading up on old Grecian medicine in connection with something else, and I was amazed to find that way before the Homeric days the Greek doctor was called a *Demiourgos,* that is, a worker for the people, and through all these centuries, gentlemen, you have been *Demiourgoi,* working for the people. It was only in the second stage of medicine that you became the *Iatrouantheis,* the physician-prophet, and only after the Trojan War did the doctor get the title by which he goes today in Greece, and that is the *Iatros,* the physician. Gentlemen, there is a significance in that stratification of responsibilities. From the earliest days, the foundation was laid for you to be helpers of the people. Gentlemen, I have a great, great admiration and love for the American Medical Association, and it has been one of the great honors of my life that the medal that I am wearing this morning has been granted to me through your generosity. It means so much to me, and thank God that I have had the opportunity of appearing at least once before this great House of Delegates. Thank you very much.

Report of the Secretary

Dr. George F. Lull, Secretary, presented his report (see The Journal, Nov. 7, 1953, pp. 926-928), which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of the item relating to a Resolution on Payment of Back Dues introduced at the New York meeting, which was referred to the Reference Committee on Amendments to the Constitution and Bylaws.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John J. Masterson, Chairman, presented the following report, which was adopted:

Membership: It was very gratifying in reading the report of the Secretary, that the paid membership as of Aug. 31, 1953, was 117,063, an increase of 7,323 members over the corresponding period in 1952. This increase in membership is concrete evidence of the confidence of the profession in the policies of the Association and our endeavors in promoting and improving the health and well being of the American public. We are pleased to learn that plans are being made to expand the use of the I.B.M. system during 1954 in order that the membership cards may be sent at the time the dues are recorded. The installation of this system will avoid many complaints regarding delay in receiving membership cards and also in receipt of The Journal or one of the specialty journals by new members.

The Secretary makes reference to another problem, which is the variety of membership classifications in constituent associations, resulting in confusion as to the type of membership a physician may hold in the American Medical Association. The problem arises out of provisions in the constitutions and bylaws of the constituent associations, and for that reason cannot be easily or quickly solved. Another source of misunderstanding is the use of various terms to designate categories of membership. Your committee is pleased to note that the Secretary has undertaken a new survey of the constitutions and bylaws of constituent associations with respect to provision for exemption from payment of American Medical Association dues, and that further recommendations can be made at completion of the study.

Subscription and Circulation: The number of subscribers to The Journal was about the same as in 1952, although many members substituted one of the special publications in place of The Journal. All of the nine publications showed an increase in circulation.

Field Activity: Many invitations are received by the Secretary and Assistant Secretary to address meetings of state and county medical societies and other organizations which maintain cordial relations with the American Medical Association. These invitations are accepted whenever possible, notwithstanding that such attendance places an additional burden of work on their return to headquarters.

Directives of the House of Delegates: The Secretary has made disposition of resolutions adopted by the House of Delegates at the New York meeting. His report on the Resolution on Payment of Back Dues has been referred to the Reference Committee on Amendments to the Constitution and Bylaws.

Collier's Article: An article appeared in *Collier's* magazine for Oct. 30, 1953, entitled "Why Some Doctors Should Be in Jail." The Secretary wishes the record to show clearly that he never saw the article, the title, the illustrations, or the cover page before publication. Had it been submitted to him, he would have protested strongly.

In conclusion, your reference committee believes that the House of Delegates would be remiss at this time if it did not express its gratitude, appreciation, and thanks to our Secretary and Assistant Secretary and all the headquarters personnel in the office and mechanical departments for their continued loyal and faithful service in administration of the affairs of the Association.

Report of Reference Committee on Amendments to the Constitution and Bylaws

Dr. William L. Benedict, Chairman, presented the following report, which was adopted:

Your committee has considered that portion of the report of the Secretary on payment of back dues. This refers to a resolution presented to the House of Delegates in June, 1953, by Dr. George A. Earl of Minnesota concerning the payment of membership dues. This committee presents a substitute resolution as follows:

Resolved, That any active member of the American Medical Association who failed to pay dues for the year 1950, and who was suspended for such delinquency, may be reinstated during the first six months of 1954 by the payment of 1954 dues only. Should such an individual fail to pay his 1954 dues by July 1, 1954, he shall continue to be considered delinquent.

Your committee further recommends that the Bylaws of the American Medical Association be so amended as to implement this provision.

Report of Board of Trustees

Dr. Dwight H. Murray, Chairman, presented the report of the Board of Trustees (see THE JOURNAL, Oct. 31, 1953, pages 829-854, and Nov. 7, 1953, pages 928-940), which was referred to the Reference Committee on Reports of Board of Trustees and Secretary with the following exceptions:

To the Reference Committee on Legislation and Public Relations, Report of Committee on Legislation and Report of Assistant to General Manager, Department of Public Relations.

To the Reference Committee on Industrial Health, Report of Council on Industrial Health.

To the Reference Committee on Medical Military Affairs, Report of Council on National Emergency Medical Service.

To the Reference Committee on Insurance and Medical Service, Report of Council on Rural Health.

To the Reference Committee on Hygiene and Public Health, Report of Committee on Mental Health and Report of Bureau of Health Education.

To the Reference Committee on Sections and Section Work, Report of Bureau of Exhibits.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John J. Masterson, Chairman, presented the following report, which was adopted:

Report on Matters Referred by House of Delegates: With respect to that section of the report which has to do with resolutions referred to the Board of Trustees, your committee finds that in each and every instance they have been studied by the Board of Trustees and referred to the proper Committee or Council or person for action, or have been implemented by the Board of Trustees in accordance with the recommendations of the House of Delegates.

The Journal, Specialty Journals, Library, Today's Health: THE JOURNAL is ever-enlarging and continuously expanding in the diversification of reading matter. Valuable and interesting new departments are constantly being added. THE JOURNAL continues to increase its effectiveness internationally by ever-increasing international circulation and the inclusion for American readers of increasing numbers of articles of scientific and general interest. Its publication figure has now reached 167,000 copies per week.

Special attention is being given by the Editor to improve the specialty journals. The program as laid out will, it is believed, markedly improve the editing policies. Also, greater efficiency in production will no doubt be realized by the efforts being made in the field of training personnel. Financial improvement is anticipated by improvement in sales policies. The specialty journals are constantly increasing in circulation, which in the opinion of your reference committee, is evidence of ever-increasing improvement.

The Library is mentioned in this report only to call your attention to its continuous growth; 4,065 volumes are now in the Library. Extensive, valuable files and indexes of THE JOURNAL, authors, specific subjects, book reviews, etc., have been arranged for efficiency and accessibility. The Library is in a position to render valuable service to the members of the profession.

The magazine *Today's Health* is, in the opinion of your committee, an exceedingly important and efficacious medium in the public relations and public education in health functions of the American Medical Association. Despite this importance, your committee believes that it cannot fulfill its purpose at the present time because of insufficient circulation. The total subscription to *Today's Health* at present is 260,000. Of this total, it is disappointing to learn that only 26,000 members of the profession subscribe to this magazine. An annual deficit results from this situation to the extent of $150,000, and it is a serious question whether this valuable medium can be continued. It is urgently requested that the members of the profession seriously consider supporting *Today's Health* by subscribing to it. Your committee is informed that if the number of physician subscriptions were raised to 100,000, the present deficit could be eliminated. Your committee also urgently recommends that efforts be made by component medical societies to increase subscriptions to *Today's Health.*

Report of Washington Office: In the opinion of your committee, this report requires no critical analysis. The service rendered by the Washington Office has been most valuable to the profession. To read its regular reports is to determine the many services it renders. The accomplishments of this office since its beginning must be known to each member of the House of Delegates. In the opinion of your committee, the initiation of this service in Washington has been one of the best investments of the profession. We are grateful to its Director, Dr. Frank E. Wilson, and declare our wholehearted approval of his efforts.

The effectiveness of the Washington office is dependent on hometown utilization of the information supplied by the Washington Office. Your committee recommends that the members of the House of Delegates make every effort to present the medical viewpoint on all legislative information supplied by the Washington Office to their representative members of the Congress of the United States.

Report of Committee on Medicolegal Problems: In the field of medicolegal problems, which has always been a too little understood facet of practice by our profession, much has been done to clarify and bring to the profession its importance. Particularly is this true in the prevention of malpractice actions. Considerable information has been made available to the profession regarding its rights, duties, and obligations. Dissemination of scientific knowledge on the subjects of preventable dangers of blood transfusions and the accurate diagnosis of acute alcoholism has been emphasized. In the field of forensic pathology, the subcommittee has cooperated with various legislative bodies in an effort to have established uniform state laws that would create a model medical examiner law. The importance of this requires no additional comment by your reference committee.

The interrelationship of the Committee on Medicolegal Problems and the Bureau of Legal Medicine and Legislation is a happy situation. This cooperation, it is hoped, will continue.

Report of Bureau of Legal Medicine and Legislation: The Bureau of Legal Medicine and Legislation, because of its long experience and accumulation of legal information, is in a position to, and does, render to the profession valuable services. The Bureau's cooperation with the Federation of State Medical Boards of the United States in an effort to improve and more nearly approach uniformity of the various medical practice acts is to be commended.

It is interesting to note in the report of the Bureau that in the state of Ohio the decision of the attorney general of Ohio leaves no doubt as to when a hospital is illegally practicing medicine. This opinion is parallel to the position taken by the American Medical Association and many of its component societies.

Continued study is being made by the Bureau, in conjunction with the Council on Medical Service, into the subject of medical liability insurance rates charged by the insurance carrier of malpractice insurance. This study, although not completed, is evidently being continued with progress. However, because of the ever-increasing premiums charged for malpractice insurance protection and, more important, the increasing reluctance of insurance carriers to continue the availability of this protection, your committee recommends that the Board of Trustees make every effort to improve this deteriorating situation as soon as possible.

Report of Council on Pharmacy and Chemistry: The evaluation of new drugs and the drug acceptance program of this council have been a most practical and useful project provided by the American Medical Association for the individual practitioner of medicine. Likewise, its publications and reports are of great clinical value. Particularly to be commended is the report of the Committee on Research, reporting the cooperative investigations with various pharmaceutical manufacturers. The grants-in-aid through the Committee on Research is a most remarkable example of the altruistic aims of modern medicine as expressed through its official organization.

Report of Committee on Cosmetics: The report of the Committee on Cosmetics demonstrates again the opportunity for the medical profession, through its agencies, to develop close cooperation with better business bureaus and other organizations and agencies for the public good.

Report of American Medical Association Laboratories: The Chemical Section of the Laboratories establishes standards for remedial products, makes available to the profession information relative to New and Nonofficial Remedies, and cooperates in an advisory capacity with other agencies of the Association. The special problem relative to the study of cigarettes has aroused public interest, and further improvement of analytical methods and techniques is to be encouraged.

The Microbiologic Section is a department that serves to study bacteriologic problems relative to medicinal remedies and also offers a very practical future for cooperation with certain food industries.

Report of Council on Physical Medicine and Rehabilitation: This council has continued its investigations of appliances and methods for aiding those handicapped by loss of important body functions and has actively disseminated information to the medical profession and to the public on the value and use of such aids. It has continued its interest in the education of physical and occupational therapists.

Report of Council on Foods and Nutrition: This council has concerned itself with the evaluation of certain foods prepared for use in low sodium and weight-reducing diets, the proper investigation of which will lead to more accurate and dependable labeling and a wider knowledge of the variety and types of foods available for such therapeutic use. The recognition of the valuable work of Dr. William H. Sebrell by the Council in recommending him for the Joseph Goldberger Award is a tribute to the work done in the field of clinical nutrition. The pioneering work of the Council on evaluating the use of vitamin and nutrient enriched foods serves as a further reminder of the outstanding and enviable position of this Council in its service to the public. Death and illness have necessitated changes on this council and further illustrate the toll of hard work and devoted service that has so often characterized membership on councils of the American Medical Association.

Report of Bureau of Investigation: The never-ending exposure of quacks, cultists, patent medicines, and similar fads, agents, and appliances has been carried on in increasing degree, and probably more effectively owing to the use of radio, television, and other means of public information dissemination.

Report of Bureau of Medical Economic Research: This has proved to be one of the most valuable departments of the American Medical Association. It has done more to give the public and the profession accurate and honest factual data on medical economic problems and by so doing has successfully refuted much of the socialistic philosophy which has been rampant in the United States in recent years. By so doing it has accomplished a great deal toward the preservation of freedom in our country. Because of the accuracy of its findings and conclusions, it has gained the confidence of many outside the medical profession. Its director has proved himself to be a competent, honest economist, and for his leadership and the work of this bureau we are sincerely appreciative and most grateful.

Report of Bureau of Industrial and Personnel Relations: This bureau has established a pattern for the proper regulation of its employee relationships to the Association. It has done a most creditable job in fostering the type of program for its employees that leads to harmonious, cooperative effort so important to an organization dependent on a large number of persons for efficient operation.

The report of the Board of Trustees, covering 135 pages in the Handbook of the House of Delegates, is an indication of the great amount of work required of the Board. A perusal of the report is eloquent testimony to the loyal and selfless devotion of the members of the Board of Trustees to the duties of their office. They spend many days and long hours in working on the affairs of the Association. Your committee does not think that any other organization has a more faithful Board of Trustees. We owe them our deep gratitude, sincere thanks, and appreciation.

In conclusion, may we convey to the other members of our committee our sincere thanks for their generous, gracious cooperation and assistance in the preparation of this report.

Report of Reference Committee on Legislation and Public Relations

Dr. Bruce Underwood, Chairman, submitted the following report, which was adopted:

REPORT OF COMMITTEE ON LEGISLATION

Resolution on Social Security and Report of Committee on Legislation on Jenkins-Keogh Bills (H. R. 10 and H. R. 11): Your committee carefully considered resolution No. 10 on the subject of social security, introduced by Dr. Willard A. Wright, North Dakota, and the Report of the Committee on Legislation of the Board of Trustees on the Jenkins-Keogh bills. The purpose of these bills is to eliminate the discrimination and inequities which exist under present tax laws by extending the tax deferment privilege to the country's 10 million self-employed and also to millions of employees who are not covered by pension plans. The purpose of the resolution is to reaffirm our support of the voluntary pension program provided in the Jenkins-Keogh bills and to reaffirm our strong opposition to the extension of compulsory coverage of physicians and other self-employed persons under Title II of the Social Security Act. Your committee recommends the adoption of the resolution.

Legislation to Amend the Constitution of the United States Relative to the Making of Treaties and Executive Agreements (S. J. Res. 1): Your committee endorses the efforts that have been made to secure a favorable action concerning this legislation. We are glad to note that it has been reported favorably by the Senate Judiciary Committee and that it is now awaiting action by the Senate. Your committee urges continued efforts to secure favorable action on the resolution.

Legislation Concerning Transfer of Functions, Responsibilities, and Duties of Department of the Interior and Bureau of Indian Affairs Relating to Health and Hospitalization of Indians to United States Public Health Service (H. R. 307 and H. R. 1057): Your committee endorses the action taken to date with respect to this legislation and urges continued efforts to secure favorable action.

Legislation to Authorize United States Public Health Service to Admit to Its Hospitals Persons Committed by State Courts Who Are Beneficaries of the Service or Narcotic Addicts (H. R. 3204): Your committee endorses the action of the Committee on Legislation and the Board of Trustees in recommending the enactment of this legislation.

Legislation Concerning Deduction of Medical and Dental Expenses for Income Tax Purposes (H. R. 3375): Your committee endorses the action of the Committee on Legislati and the Board of Trustees in actively approving the princi involved in this legislation. It urges that efforts be continued to secure a greater measure of relief for those individuals who have suffered from the financial burden resulting from the expense of a serious long-term illness by reducing or removing the limitation on the deduction of medical and dental expenses for income tax purposes which are imposed by existing law.

Legislation Concerning the "Doctor-Draft" Law (H. R. 4495): The "Doctor-Draft" law was extended for two years and will now expire on June 30, 1955. The Committee on Legislation and the Board of Trustees recommended that the "Doctor-Draft" law be extended for only one year, but this recommendation was not followed, and on June 29, 1953, the legislation became Public Law 84 (83rd Congress). Your committee endorses the vigorous actions taken by the Committee on Legislation and the Board of Trustees to date. Your committee feels strongly, however, that there should be no further extension of the "Doctor-Draft" law. It feels that the legislation is discriminatory and urges the Committee on Legislation and the Board of Trustees to oppose actively any further extension of the "Doctor-Draft" law.

Legislation Concerning Reorganization of Department of Defense (Reorganization Plan No. 6): Your committee considered this legislation and noted that it became effective on June 30, 1953. It noted that the position of Assistant Secretary of Defense (Health and Medical) had been filled by a Doctor of Medicine, Dr. Melvin A. Casberg, even though the legislation did not specifically require that a Doctor of Medicine be appointed. Your committee hopes that in the future the position will continue to be filled by a Doctor of Medicine.

Regional Legislative Conferences: Your committee feels that the regional legislative conferences were of value and that they should be continued. It feels it is important to have direct personal contact with members of state and local medical societies in order to know their opinions in regard to federal legislation.

Report of Committee on Legislation in General: Your committee noted that during the year reported, the Committee on Legislation held six meetings, analyzed 259 legislative proposals and recommended policy positions on 210 of these measures to the Board of Trustees. We commend the Committee on Legislation for its fine work. While most of its report was reported satisfactorily, your committee wishes to recommend that in the future all items include a statement concerning (1) the present status of the legislation and (2) the nature of testimony given which would clearly indicate the position of the Association. We feel this information should be given for all items of legislation, so that the entire membership of the House of Delegates may be fully informed.

Report of Assistant to General Manager—Department of Public Relations

Public Relations Program for 1953: Your committee endorses the program which has been adopted and the objectives listed. It endorses efforts to reach medical students, interns, and residents and feels these efforts should be continued and expanded. It commends the Department of Public Relations for the fine work it is doing with a staff of 20 employees.

Advisory Committee: Your committee noted that the Advisory Committee to the Director of the Department of Public Relations is concerned only with operational procedures and that all policy decisions are made by the House of Delegates and by the Board of Trustees. It noted that the Assistant Secretary of the Association, and frequently a member of the Board of Trustees sits in on the meeting of the Advisory Committee, and that all recommendations of the committee that involve policy are referred to the Secretary and General Manager, who transmits them to the Board of Trustees for action.

Press Relations: Your committee spent much time in considering this subject and feels it is of the utmost importance to cooperate with the members of the press, radio, and television. We noted that cooperation paid great benefits in mutual trust and understanding and that many difficulties were solved in this manner. We noted that there were 185 reporters and writers at the annual meeting in New York in 1953 as compared to 110 at the 1952 annual meeting in Chicago. W noted the complimentary remarks which have been made cor cerning the press relations of the American Medical Ass ciation. Your committee urges continued cooperation with th press at national, state, and local levels in order to secure greater mutual trust and understanding of the many problen involved.

Public Relations Conferences: Your committee endorses tl holding of public relations conferences and recommends the continuance. It urges, however, a greater participation doctors of medicine in these conferences.

Daily Bulletin: Your committee noted that 8,000 copies the Daily Bulletin were distributed at the annual meeting New York in 1953 and that 3,000 copies will be distribut at the St. Louis Clinical Meeting this year. It notes the in provements which have been made in the bulletin and the i creased information given concerning the work of the Hou of Delegates. Your committee commends these efforts, a expresses appreciation for them, and recommends the co tinuance of the Daily Bulletin.

Radio and Television Shows: Your committee endorses t fine work that is being done with the promotion of radio a television shows and believes this work is of great value a should be continued and expanded.

Literature: Your committee discussed this subject at leng and feels that much good work is being done in the prepa tion, promotion, and distribution of literature. It notes, ho ever, that the Department of Public Relations does not ha any adequate method of determining the value and effecti ness of its work. Your committee believes it is of value a is effective, but recommends that the Board of Trustees esta lish some procedure to measure its effectiveness. It is su gested that the field service might be used to some extent this connection.

Other Services: Your committee feels that the P. R. Doct the press service which was established for the President, t Presidential Inaugural Ceremony in 1953, the field service, a the guided tours of the Chicago headquarter's office are wort of special praise and commendation. Your committee co mends the Public Relations Department for its long-ran program in telling the positive side of American medicin program with its myriad services and activities.

Report of Reference Committee on Industrial Health

Dr. Frank A. MacDonald, Chairman, submitted the fo lowing report, which was adopted:

Your Reference Committee on Industrial Health has ca fully studied the report of the Council on Industrial Heal and was impressed with the extensive scope of the activiti of this council. It was also impressed with the large numb of pilot studies being undertaken by this council in the fiel of disease and accident prevention, and in health educatio Your committee agrees with the scope and objectives of th council and urges that it continue with its studies in industri and community health councils, in health and welfare pla and in the professional aspects of sickness absenteeism a workmen's compensation.

Report of Reference Committee on Medical Military Affairs

Dr. William A. Hyland, Chairman, presented the followi report, which was adopted:

With regard to the report of the Council on Nation Emergency Medical Service in the report of the Board Trustees, your committee feels like many of the delegates wh appeared before it complimenting most highly the though detail, and mode of expression of the subjects. As a commi tee we also commend the Board and the Council for th excellent treatise.

Report of Reference Committee on Insurance and Medical Service

Dr. John M. Porter, Chairman, submitted the followin report, which was adopted:

The report of the Council on Rural Health speaks for i self and should be read by all of us who practice outsid the metropolitan or industrial centers. If, because of isolation and sometimes apparently radical thinking, the farmer seems to require more than his share of attention or even subsidization, certainly we must agree that no better friend of medicine or more fundamentally necessary individual exists. In the opinion of your reference committee, the work of the Council on Rural Health with its emphasis on education and its admirable record of cooperation with farm groups should be continued and its efforts commended.

Report of Reference Committee on Hygiene and Public Health

Dr. Thurman B. Givan, Chairman, presented the following report, which was adopted:

Report of the Committee on Mental Health: The reference committee commends the Committee on Mental Health (because it is a comparatively new committee, having its first meeting in March, 1952) for the elaborate program it has set out to accomplish. If it can accomplish the raising of the standards of care and treatment of patients in mental institutions, it will have done yeoman work. Your committee recommends that the appointment of a new subcommittee dealing with alcoholism, when a proper survey has been completed, should be effected as soon as possible. Your committee recommends approval of the report as published.

Report of Bureau of Health Education: Your committee has reviewed the report of the Bureau of Health Education and has discussed the subject matter very extensively with Dr. W. W. Bauer. We are tremendously impressed with the vast scope of the work of health education and recommend its continuation and expansion to meet this great need of the American public under Dr. Bauer's direct supervision. We especially commend the cooperation between the American Medical Association and other health organizations, including Secretary Oveta Culp Hobby's Department of Health, Education and Public Welfare, and also the National Committee for Traffic Safety, National Citizens Committee for Educational Television, National Committee on Boys and Girls Club Work, and many other assignments.

Report of Reference Committee on Sections and Section Work

Dr. Jesse D. Hamer, Chairman, submitted the following report, which was adopted:

A review of the report of the Bureau of Exhibits indicates the vast scope of work carried out by this bureau. Not only did it provide many physical exhibits of interest to the general practitioner at the Clinical Meeting in Denver last December, and 260 exhibits at the Annual Meeting in New York last June, with material of high quality and great teaching value to members of the 20 sections of the Scientific Assembly, but also, with the Committee on Medical Motion Pictures, it arranged for the presentation of many films, which were shown to large groups in all instances. Your committee was pleased to note that there are now 50 subjects covered by prepared exhibits, which depict the activities, aims, and purposes of the various councils and bureaus of the Association. These fall into two general groups: (1) medical exhibits for medical societies and other scientific groups and (2) health exhibits for fairs, expositions, and other public gatherings. These exhibits have increased by 12 during the past year.

It is apparent in the report of this bureau that increasing interest continues in the field of motion pictures so that the film library, the film reviews, and films for television assembled by the Committee on Medical Motion Pictures have shown a substantial increase in numbers and more widespread usefulness. Your committee would call to the attention of the House that the secretary of the Committee on Medical Motion Pictures visited Mexico and the First World Conference on Medical Education in London during the past year, and addressed a number of scientific assemblies on the subject "The Effectiveness and Use of Motion Pictures in Medical Teaching."

Your committee wishes to commend the members of the Bureau of Exhibits and of the Committee on Medical Motion Pictures for their excellent work and accomplishments during the past year, and to recommend to the House that the combined report be accepted.

Supplementary Reports of Board of Trustees

Dr. Dwight H. Murray, Chairman, presented the following supplementary reports of the Board of Trustees.

The Speaker referred items A, B, C, K, and N to the Reference Committee on Reports of Board of Trustees and Secretary; items D and G to the Reference Committee on Hygiene and Public Health; items E, F, H, I, and J to the Reference Committee on Medical Military Affairs; and items L and M to the Reference Committee on Medical Education and Hospitals.

A. 1956 ANNUAL MEETING

In accordance with the authority granted by the House of Delegates at its meeting in June, 1953, the Board of Trustees investigated the accommodations in the several cities from which invitations emanated and has selected Chicago, during the week of June 11 to 15, as the place for the 1956 Annual Meeting of the Association.

It is becoming increasingly difficult to select a place for the Annual Meeting which meets the requirements of the Association and at the same time offers a date most appropriate for the needs of the profession. It is recommended, therefore, that the place of the Annual Meeting be selected five years in advance, rather than three, as it is at the present time.

B. MEDICAL PROGRESS DAY

At the June, 1953, meeting of the House of Delegates a resolution was introduced by Dr. R. J. Azzari of New York, recommending that a Medical Progress Day be proclaimed. Following receipt of a report from the Department of Public Relations and its Advisory Committee, the Board of Trustees recommends that no action be taken on the resolution. It is the feeling of the Board that the institution of a Medical Progress Day on a nationwide basis cannot be accomplished at this time. It is suggested that if the constituent state and component county societies wish to promote such a day locally they do so whenever possible.

C. RESOLUTION ON CRIPPLED CHILDREN'S PROGRAMS

The resolution on Crippled Children's Programs introduced into the House of Delegates in June, 1953, by Dr. Cleon A. Nafe of Indiana, was referred to the Washington Office of the Association. The resolution was brought to the attention of the Secretary of the Department of Health, Education, and Welfare with the request that the section of the regulations cited in the resolution be eliminated. The reply received indicated that the request of the Association would be given careful consideration in the department's exploration of the questions raised by the resolution.

K. WORLD MEDICAL ASSOCIATION

The World Medical Association held its Seventh General Assembly in The Hague, Holland, Sept. 1 to 6, 1953. The delegates from the American Medical Association were Drs. Gunnar Gundersen and Edwin S. Hamilton. The alternate delegates were Drs. F. J. L. Blasingame and Dwight H. Murray. There were also 71 members of the United States committee in attendance as observers besides the American doctors who are officials of the organization. The assembly was the best attended of any. One of the important decisions was to endeavor to coordinate and take the leadership in a world-wide movement to improve the standards of industrial and occupational medicine.

Dr. Austin Smith was named by the council to fill the vacancy in the council caused by the death of Dr. Elmer L. Henderson. This was later confirmed by the assembly. Dr. Gunnar Gundersen was elected to the council to replace Dr. R. L. Sensenich. Dr. Louis H. Bauer remains as secretary general. Considerable discussion took place about the bulletin, and the assembly directed the council to appoint an advisory editorial board composed of three members plus an executive editor, also to be appointed by the council, and the secretary general as business manager. The council appointed the following advisory board: Dr. Paul Cibrie, secretary of the French Medical Association; Dr. Hugh Clegg, editor, *British Medical*

Journal; Dr. Lorenzo Garcia-Tornel, secretary of the Spanish Medical Association, Dr. Austin Smith, editor of THE JOURNAL of the American Medical Association, was designated as executive editor, replacing the former editor. It is contemplated that there will be considerable change in format and the publication will be increased in frequency.

Prior to the General Assembly the First World Conference on Medical Education was held in London. This was sponsored by the World Medical Association. It was attended by 617 registered participants from 62 countries and representing 127 universities and medical schools. Besides obtaining the viewpoints of medical education, medical associations, and government bodies, it endeavored to obtain the viewpoint of the practicing physician on medical education. There was a large delegation from the United States attending the Conference. Dr. Victor Johnson was one of the vice presidents of the conference; Drs. Herman G. Weiskotten and Donald Anderson of the Council on Medical Education and Hospitals, and Mr. Ralph Creer of the headquarters office presented papers, as did several other American doctors.

An attempt is being made by various groups to draft a code of international medical law. None of these groups has any competence in the matter. The World Health Organization was asked by the Belgian government to take action in the matter. The health assembly instructed its director general to undertake a study with the assistance of appropriate organizations and persons and to report back. W. H. O. invited the W. M. A. to take part in this study and stated that W. H. O.'s part seemed to be one of coordination. The stand of the World Medical Association is that any code of international medical law governing the actions of doctors in peace or war must necessarily be based on medical ethics; further, that the medical profession is the only one competent to draw up such a code of ethics; that jurists and governments and governmental agencies should have no part in such a procedure except, perhaps, to give the code legal status after adoption. The World Medical Association has already adopted an International Code of Medical Ethics which has received the approval of this House of Delegates. It is now drafting an additional chapter on the Duties of the Doctor to Society. The World Medical Association has given notice to all concerned that the medical profession will never accept a code of ethics which has been drafted by jurists or governmental agencies.

The Board of Trustees has continued its support of the World Medical Association, as it feels it to be a very necessary organization in that it is the only organization on an international level which can speak for the practicing profession. All other international organizations that deal with socioeconomic or educational problems are governmental. The World Medical Association needs financial support. While the dues of member associations are being doubled and supporting committees are developing in other countries, nevertheless for some time to come the majority of the financial support must come from the United States. The United States Committee, Inc., has tripled its membership since a year ago, but it must triple its present membership in order to be self-sustaining in the activities it has agreed to sponsor. The Board of Trustees hopes that the members of the American Medical Association will lend their support to the World Medical Association by joining the United States Committee.

N. APPRECIATION

It is my privilege now to extend my thanks and appreciation to the members of the Board of Trustees for their very intelligent work and for the contributions they are making to the progress of medicine. The long hours and many days they spend in working on the affairs of the Association are done willingly and graciously without a murmur of complaint. The President and President-Elect, by their numerous trips across country to visit the state and county associations, are deserving of great praise and commendation. It seems that more and more these two offices have become full-time jobs for these men. Also may I express appreciation to the headquarters staff who are capable, thoughtful, and diligent in their services and w[illegible] ready at all times to assist the members of the prof[illegible]

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John J. Masterson, Chairman, presented the following report, which was adopted:

1956 Annual Meeting: Your reference committee approves the selection of Chicago for the 1956 Annual Meeting, during the week of June 11 to 15. It also approves the recommendation of the Board of Trustees that the place of the Annual Meeting be selected five years in advance, rather than three, as it is at the present time.

Medical Progress Day: Your reference committee concurs in the recommendation that no action be taken on this resolution, as it is the feeling of the Board of Trustees that the institution of a Medical Progress Day on a nationwide basis cannot be accomplished at this time. The Board suggests, however, that, if the constituent state and county societies wish to promote such a day locally, they do so whenever possible.

Resolution on Crippled Children's Programs: The resolution on this subject was introduced at the June, 1953, meeting of the House of Delegates. It was brought to the attention of the Secretary of the Department of Health, Education, and Welfare. The reply received indicated that the request of the Association would be given careful consideration in the department's exploration of the question raised by the resolution. This report is for your information only, and carries no recommendation.

World Medical Association: The first page of this supplementary report is mostly informative of the Seventh General Assembly of the World Medical Association in The Hague, Holland, Sept. 1 to 6, 1953. The delegates from the American Medical Association were Drs. Gunnar Gundersen and Edwin S. Hamilton. The assembly was the best attended meeting of the World Medical Association.

Prior to this meeting, the First World Conference on Medical Education was held in London. The conference was sponsored by the World Medical Association and was well attended. A large delegation from the United States was present.

> An attempt is being made by various groups to draft a code of international medical law. None of these groups has any competence in the matter. The World Health Organization was asked by the Belgian government to take action in the matter. The Health Assembly instructed its Director General to undertake a study with the assistance of appropriate organizations and persons and to report back. W.H.O. invited the W.M.A. to take part in this study and stated that W.H.O.'s part seemed to be one of coordination.
>
> The stand of the World Medical Association is that any code of international medical law governing the actions of doctors in peace or war must necessarily be based on medical ethics; further, that the medical profession is the only one competent to draw up such a code of ethics; that jurists and governments and governmental agencies should have no part in such a procedure except, perhaps, to give the code legal status after adoption.
>
> The World Medical Association has already adopted an International Code of Medical Ethics which has received the approval of this House of Delegates. It is now drafting an additional chapter on the Duties of the Doctor to Society. The World Medical Association has given notice to all concerned that the medical profession will never accept a code of ethics which has been drafted by jurists or governmental agencies.

The Board of Trustees has continued its support of the World Medical Association. It is the only organization on an international level which can speak for the practicing physician, and it is hoped that the members of our Association will lend their support to the World Medical Association by joining the U. S. Committee.

Appreciation: Your committee fully concurs with Dr. Dwight H. Murray, Chairman of the Board of Trustees, in expressing his appreciation to the other members of the Board of Trustees, the President and President-Elect, and members of the headquarters staff for their valuable contribution to the Association. Dr. Murray's modest effacement of his own contribution is a merited example of fine leadership.

D. RESOLUTION ON AMENDMENT OF FEDERAL NARCOTIC ACT TO PROVIDE FOR DISPENSING OF CODEINE MIXTURES AND COMPOUNDS ON ORAL PRESCRIPTIONS

Acting on the recommendation of the Reference Committee on Hygiene and Public Health, adopted by the House of Delegates in June, 1953, the Board of Trustees referred to the Council on Pharmacy and Chemistry the resolution introduced by Dr. Raymond M. McKeown of Oregon.

Communications were sent to the Bureau of Narcotics and several organizations interested in this field asking for an expression of opinion as to the advisability of a change in the Federal Narcotic Law at this time to provide for the dispensing of codeine mixtures and compounds on oral prescriptions. In the reply received from the Bureau of Narcotics it was stated, and this was concurred in by the other groups, that the bureau "would favor an amendment to permit the filling of oral prescriptions for compounds of certain narcotic drugs that, as compounds, presented comparatively little or no potential for creating or gratifying drug addiction" and would apparently support "an amendment to authorize this Bureau (after considering any views on the subject expressed by the Surgeon General, U. S. Public Health Service; the Commissioner, U. S. Food and Drug Administration; State Narcotic Control Officers; and the respective secretaries of a national association representing (a) narcotic drug manufacturers, (b) physicians, and (c) pharmacists) to establish by regulation a list of the drugs and compounds found to possess relatively little or no addiction liability. The oral prescription exception is intended to be applicable to substances on this list." The bureau is in the process of preparing such a text embodying the above-stated principle. It was further stated that the extension of the oral prescription classification to mixtures and compounds of the potentially dangerous opium derivatives will inevitably be subverted by drug peddlers and drug addicts who will take advantage of the procedure to obtain, by deception, quantities of the addicting compound.

In view of the above, the Board of Trustees recommends that the Association do not seek a change in the Federal Narcotic Law at this time.

G. RESOLUTION ON ADVERTISING OF MEDICAL PRODUCTS

In accordance with the directive of the House of Delegates in June, 1953, the Board of Trustees considered the Resolution on Advertising of Medical Products, introduced by Dr. W. C. Stover of Indiana, and makes the following report in this regard:

For almost 50 years the Council of Pharmacy and Chemistry has served as a standing committee of the Board of Trustees of the American Medical Association and in this capacity has exercised supervisory influence over the statements made in the advertising appearing in the publications of the American Medical Association. In fact, the principles which govern the acceptance of products for advertising in American Medical Association publications read in part:

> Medicinal preparations, to be admissible for advertising, must stand accepted by the Council on Pharmacy and Chemistry, except when such products may be determined by the Council as not coming within its purview.
>
> Apparatus or physical appliances used for therapeutic purposes must be accepted by the Council on Physical Medicine and Rehabilitation before being advertised in A. M. A. publications, except when such products may be determined by the Council as not coming within its purview.
>
> Food products for which health claims or special dietetic qualities are featured must be accepted by the Council on Foods and Nutrition to be eligible for advertising except when such products may be determined by the Council as not coming within its purview.
>
> Cosmetic preparations and soaps must stand accepted by the A. M. A. Committee on Cosmetics to be admissible for advertising.

Other principles read in part:

> Advertisements will not be accepted which, either by intent or inference, would result in deceiving, defrauding, or misleading the reader.
>
> Sweeping superlatives or unfair comparisons should be avoided. Any claims for superiority must be supported by sound evidence. Extravagantly worded copy is subject either to revision or to rejection.
>
> Quotations or excerpts from published papers are not accepted if by themselves they distort the true meaning intended by the authors, or are otherwise misleading.

All advertising concerning any products which fall within the purview of any standing committee of the Board of Trustees is referred to the office of the committee for comment and criticism before it is published. Comment is provided by the office on the basis of general opinions previously expressed by the committee and on the statements contained in advertising material already declared acceptable by the committee or council. Only then is the advertising, modified or otherwise, included in THE JOURNAL or any of the American Medical Association publications. It is not possible for the Editorial Department or the Advertising Department to pass on all advertising copy, and therefore the value of the Council's work in this respect is obvious.

Each council consists of members who are nationally or internationally known and who are considered experts in their fields. Collectively they are able to pass judgment on problems that might be subject to considerable difference of opinion if left to individual consideration. There are times when articles appear in a medical journal which would appear to be at variance with claims declared acceptable by the council; however, the councils give consideration to all published papers and to all of the evidence and for this reason are considered as giving generally acceptable advice. If anything, the councils have been accused of being too conservative. However, when one is dealing with potent drugs a conservative attitude is justified.

The Board of Trustees believes that the supervision exercised over the advertising in American Medical Association publications is in keeping with today's needs. It believes that the members of these councils provide sound and supportable opinions, and that such expert guidance offers as dependable assurance concerning advertising claims within the American Medical Association publications as is possible to achieve. At this time, no other effective system whereby advertising principles can be applied can be envisaged.

Report of Reference Committee on Hygiene and Public Health

Dr. Thurman B. Givan, Chairman, submitted the following report, which was adopted:

Resolution on Amendment of Federal Narcotic Act to Provide for Dispensing of Codeine Mixtures and Compounds on Oral Prescriptions: Your committee approves the recommendation of the Board of Trustees that the Association does not seek a change in the Federal Narcotic Law at this time.

Supplementary Report of the Board of Trustees on Advertising of Medical Products, and Resolution on Ethical Advertising: The supplementary report of the Board of Trustees on the Resolution dealing with advertising of medical products was carefully scrutinized and was discussed by several members, including Dr. Austin Smith, Editor of THE JOURNAL, and Dr. Robert Stormont, Secretary of the Council on Pharmacy and Chemistry. Your committee agree in principle with the resolution presented at this session by the West Virginia State Medical Association on the subject of ethical advertising but as a result of the discussion suggests the following recommendation: That the Council on Pharmacy and Chemistry be encouraged to take every opportunity to afford physicians early and complete information available on all drugs as they are produced, detailed or advertised, even before Council acceptance.

E. RESOLUTION ON "DOCTOR-DRAFT" LAW

The resolution on the "Doctor-Draft" law, introduced in June, 1953, by Dr. A. H. Aaron of New York, proposing that the recommendations of state and local medical advisory committees to the Selective Service System be made mandatory rather than advisory, was considered by the Council on National Emergency Medical Service as directed by the House on recommendation of the Reference Committee on Legislation and Public Relations. It was the decision of the Council that its previous position be reaffirmed and that the proposal be not endorsed, and in this recommendation the Board of Trustees concurs. Experience has demonstrated that in the great majority of states the recommendations of the medical advisory committees are accepted by state and local Selective Service Boards. In addition, implementation of Dr. Aaron's proposal would require an amendment to the "Doctor-Draft" law. It is the opinion of the Board that such an amendment is neither necessary nor feasible at this time.

F. MEDICAL POLICIES IN DISASTER

In 1938, following consideration of a request from the American National Red Cross for approval of medical policies in disaster, the House of Delegates agreed that the primary responsibility for the care of the sick and injured in disaster rests with the local physicians and dentists and that the functions of the Red Cross should be that of cooperation with local physicians and dentists by assisting in organizing and directing medical relief work and by providing the needed facilities that are lacking for the emergency. With regard to detailed arrangements for emergency work it was decided that these could be made by mutual agreement between the Red Cross and local medical organizations so that a standard might be set in advance.

Believing that this policy should be reviewed in the light of the establishment of the Federal Civil Defense Administration, the Board of Trustees referred the matter to the Council on National Emergency Medical Service for study and report. The Council initiated correspondence with the two groups in order to obtain the present policies of the two agencies and to determine any overlapping of responsibilities which may exist.

It is the recommendation of the Board of Trustees that the House of Delegates adopt a position in agreement with the statement of the American National Red Cross that the primary responsibility for the care of the sick and injured in disaster rests with the public health authority and local medical and allied professional organizations. It is further recommended that the function of the Red Cross should be one of cooperation with local physicians and dentists and civil defense agencies. The Red Cross should assist in organizing emergency medical relief work and provide the facilities that may be lacking.

In general, the Board recommends the approval of the principles and practices outlined in current disaster policies of the Red Cross for the handling of the medical features of disaster relief. In view of the creation of federal, state, and local civil defense agencies, the development of uniform over-all plans is now feasible for national disaster. Detailed arrangements for possible emergencies could be made through agreements between the Red Cross, local medical organizations, and civil defense agencies so that a feasible program might be established in advance.

H. Universal Military Training Program

On Aug. 28, 1953, a statement prepared by the Council on National Emergency Medical Service and approved by the Board of Trustees was submitted to the National Security Training Commission. It is being presented to the House of Delegates at this time with the recommendation that the position recommended by the Association concerning the medical implications of a universal military training program may be affirmed. Affirmation of this statement does not in any way imply approval or disapproval of the establishment of a universal military training program.

STATEMENT OF THE AMERICAN MEDICAL ASSOCIATION TO THE NATIONAL SECURITY TRAINING COMMISSION AUG. 28, 1953

In presenting this statement, it is the purpose of the American Medical Association to make certain suggestions relative to the medical aspects of universal military training rather than to comment on whether such a program should be adopted. If the Congress, in its discretion, determines that the program is necessary, the medical profession is ready to cooperate in its implementation. We believe that we can make a contribution at this time in connection with the preliminary planning for such a program, inasmuch as the various councils and departments of the Association have been studying for some time the factors involved in the most effective utilization of medical manpower in time of national emergency and in connection with universal military training.

Last year, representatives of the American Medical Association appeared twice before the National Security Training Commission and also testified before the Armed Services Committee of the Senate and the House of Representatives. The initial report of the commission, submitted to the Congress, covered certain of the Association's suggestions; however, others were not discussed. In our appearances before congressional committees there was a tendency to discuss many of our proposals in conjunction with legislation pending at that time designed to revise the Armed Forces Reserve Program. Although Congress did not adopt the commission's recommendations, the Armed Forces Reserve Act of 1952 was enacted on July 9, 1952. Inasmuch as the act does not cover the medical aspects of universal military training as discussed in our previous statements, it is apparent that if they are to be effected, they must be included in legislation which the commission may suggest for congressional consideration.

It is the belief of the Association that the following five cardinal elements essential to the health and medical care of our nation should be considered by the commission:

(1) *The Continuation of Pre-Professional and Professional Education for Qualified Students:* It has always been the firm belief of the Association that should a universal military training program be adopted, it is imperative that safeguards be included to prevent any disruption in the education of an adequate force of professional personnel. In order to accomplish the basic underlying purpose of Public Law 51, 82d Congress i. e., to provide an adequate force of well-trained reserves, i is essential that the education of specialists be allowed to proceed without any impairment.

In its report to the Congress last year, the commission strongly recommended against split periods of training and the deferment of professional students from the six month training period. On page 28 of the report, the commission does, however, discuss the holding in abeyance of the reserve status "of a number of medical, dental and scientific students until the completion of their professional study." Inasmuch as this was one of the recommendations of the Association, we were pleased to see its favorable acceptance by the commission. However, the proposal was suggested by the commission for study only and was not included in the draft legislation which accompanied the report. With the rejection of split training periods and the deferment of professional students, this would appear to be the one remaining mechanism for insuring the uninterrupted flow of trained reserves. Therefore, the Association believes that it is imperative that this proposal be stressed by the commission in its new report and in its appearance before the congressional committees considering this legislation.

In this connection, two further points should be considered The commission's report on page 28 also notes that: "Under such an arrangement, the Reserve obligation of seven and one half years would not begin to run until *graduation from* medical, dental or scientific school." (emphasis added). It is believed that this recommendation should be changed to refer to completion of professional education rather than graduation from medical school. Such a revision would encompass the completion of internship and in some instances residency training Such an amendment would appear to be in line with the thinking of the commission, in view of the following statement which appears in the same paragraph as the above quoted statement: "It would also provide the Armed Forces with reservists who were qualified doctors, dentists and technicians, instead of mere apprentices in these fields."

In the implementation of this recommendation, it is essential that no advantage over civilian hospitals accrue to Armed Forces hospitals by allowing internship and residency service in such installations to count against a person's total reserve obligation. If this were permitted, the obtaining of interns and residents by civilian hospitals would be made increasing difficult.

The American Medical Association sincerely believes that a person eligible for induction into the National Security Training Corps, whose aptitude or previous accomplishments indicate that he can best contribute to the nation as a trained professional man, should be placed in a category that will permit him to continue his education, and that such a person be so classified before or at the time he reaches the age of induction. It is also believed that the selection of students and the control of educational programs should remain in the hands of the individual colleges and universities.

(2) *The Performance of Preinduction, Induction, and Periodic Reserve Physical Examinations:* Neither Public Law 51, 82d Congress, nor the initial report of the commission specifies who will perform the induction and preinduction examinations for National Security Training Corps inductees, or the periodic physical examinations, while they are members of the reserve. If any attempt is made to perform these examinations by using full-time medical personnel of the armed forces, it will be necessary to call into service a much larger number of phy-

sicians than is currently required. The possibility of a shortage of medical personnel for the civilian population of the country which might result from such a course of action can be averted. We would like to restate our earlier recommendations that such examinations be conducted by civilian physicians on a fee basis, or by reserve personnel for the purpose of maintaining a satisfactory reserve status. This system is now operating successfully with respect to the conducting of periodic physical examinations for reservists by the armed forces.

(3) *Extent of Medical Services to Be Provided for Members of the National Security Training Corps: (a) Corrective Treatment and Rehabilitation:* The American Medical Association thoroughly supports the concept that those individuals who cannot meet the physical and mental requirements established for induction into the National Security Training Corps, should, when possible, be rehabilitated, but it equally strongly opposes the idea that this responsibility belongs to the federal government. The original version of s. 1, 82d Congress, contained a section providing for the assumption of corrective treatment and rehabilitative care by the federal government. The Association feels that the deletion of this section by the Congress prior to the enactment of s. 1 into law is indicative of congressional intent in this regard.

(b) Medical Care During Period of Basic Training: The treatment of injuries and sickness arising during or as a direct result of military service while in the National Security Training Corps will, of course, be a responsibility of government. It is believed that such treatment should be the same as that furnished currently to personnel of the armed forces. It is believed, however, that in light of the extremely short period of training and the favorable conditions which will prevail (i. e., no overseas assignments, no combat duty, etc.), the number of doctors per 1,000 inductees should not exceed the accepted requirements for the civilian population generally. Further, it is believed that whatever additional medical personnel is required should be obtained without enlarging the regular complement of the medical corps of the three services. With respect to the reserve personnel which will be recalled in this connection, it is recommended that a rotation system be adopted with short terms of active duty required.

(4) *Eligibility of Members of National Security Training Corps and Reserve Components for Veterans' Medical Benefits:* Though there are a variety of benefits presently available to wartime and peacetime veterans which may or may not be extended to the members of the National Security Training Corps, the American Medical Association would like to comment only with respect to medical and hospital benefits for non-service-connected disabilities. Existing provisions of law permit the treatment of certain non-service-connected disabilities in Veterans Administration facilities for persons "including veterans who served, regardless of length of service, during a period of war, (*a*) if they were discharged under conditions other than dishonorable; and (*b*) who swear that they are unable to defray the expenses of hospitalization."

In this connection, the Association is unalterably opposed to any suggestion which contemplates the extension of such care for non-service-connected conditions to members of the National Security Training Corps or other peacetime veterans. The use of the Veterans Administration facilities for such purposes would create a need for additional facilities and increased medical staffs, thereby adding to the growing strain upon the health and medical manpower resources of the nation created by the existing emergency.

The American Medical Association is in agreement with the recommendation contained in the initial report of the National Security Training Commission concerning the status of trainees with respect to veterans' medical benefits.

(5) *Source and Selection of Medical and Allied Professional Personnel:* There is considerable concern in the medical profession as to the manner of selecting the medical and allied personnel necessary to man a universal military training program and the proper agency to determine the extent of the need. This concern is predicated in a large measure on the fact that under the present proposal, all men on reaching the age of induction will be required to take basic military training and remain in a reserve component of the armed forces for seven and one-half years.

The American Medical Association is in favor of the establishment of a national civilian board, or a comparable agency, to insure the proper distribution of medical and other health reserves between civilian and military needs. Unless this is done, it will be extremely difficult to insure that such individuals serve in a manner which will contribute the most to the strength of the nation.

I. Dependent Medical Care

During the past months the Board of Trustees, as well as the Council on National Emergency Medical Service, the Council on Medical Service, and the Council on Medical Education and Hospitals, has considered the important subject of medical care for dependents of service personnel. The Board of Trustees, after reviewing a resolution on this subject from the Council on National Emergency Medical Service, submits the following statement to the House of Delegates so that a firm policy may be established by the Association in this regard:

The American Medical Association is desirous that the highest quality of medical care be provided and maintained for the entire population, including dependents of military personnel. This goal can only be realized through the greatest possible utilization of civilian community medical personnel and facilities rather than through the use of federal medical installations. The present practice of providing medical care for dependents of service personnel operates to the detriment of the community medical program. An additional result is the unnecessary and exceedingly costly expansion of military medical facilities, which, when combined with other federal medical programs, has resulted in an artificial shortage of medical and allied health personnel.

The Board, therefore, recommends that the House of Delegates adopt the following policy with respect to dependent medical care and that copies of this statement be forwarded to the President, the Secretary of Defense, and the Chairmen of the armed services committees of the Senate and the House of Representatives:

(*a*) That Congress be urged to consider carefully to define fully a national policy with respect to the provision of medical care for dependents of service personnel;

(*b*) That the Association advocate that any program devised for the care of dependents of military personnel be made contingent on the adoption of a clear and understandable definition of what constitutes a dependent;

(*c*) That the Association continue to recognize the need and importance of utilizing military medical personnel and facilities in providing hospitalization and medical care for dependents of service personnel residing outside the continental United States, and at or near military posts in the United States where civilian facilities are unavailable or inadequate;

(*d*) That except in situations as outlined in (c) above, the Association recommend that medical care and hospitalization of the dependents of service personnel be provided by civilian personnel in civilian facilities; and

(*e*) That the Association approve of the principle of premium payments by service personnel through the media of nongovernmental insurance agencies to cover the cost of medical and hospital care of their dependents through voluntary payroll deductions.

J. Report of Citizens' Advisory Commission on Medical Care of Dependents of Military Personnel (Moulton Commission)

At its meeting on Oct. 31 and Nov. 1, 1953, the Council on National Emergency Medical Service reviewed in detail the report of the Citizens' Advisory Commission on Medical Care of Dependents of Military Personnel (Moulton Commission), as well as statements from representatives of the various organizations and councils of the Association interested in the subject of dependent medical care, and submitted its recommendations to the Board of Trustees. The Board approved the report of the Council and presents the following statement with the recommendation that it be adopted by the House of Delegates:

The Board is of the opinion that the Citizens' Advisory Commission on Medical Care of Dependents of Military Personnel, under the chairmanship of Harold G. Moulton, was given insufficient time to investigate the many complex problems and issues involved in the provision of medical care for dependents of service personnel and that the commission has failed to take cognizance of the broad socialistic implications of this problem and the fact that a perpetuation or an extension of the present program transcends the interests of the Department of Defense.

In the commission's report complete emphasis has been placed on the justification and expansion of the present system rather than on determining the need for and the best method of providing dependent medical care. Also left unanswered is the question as to the extent of such dependent medical care and the serious consequences of drafting physicians under a discriminatory draft law to perform services for other civilians.

The conclusions contained in the report are not sufficiently explained or documented by substantial evidence and the recommendations would, if adopted, completely reverse the universally accepted position that civilian facilities, if available and adequate, should be utilized first and that the use of military facilities should be restricted to emergency situations and to overseas or remote areas.

The Board therefore recommends that the House of Delegates register its disagreement with the substance of the recommendations of the Moulton Commission and that its views be communicated to the Secretary of Defense and to the chairmen of the armed services committees of the Senate and the House of Representatives.

It further recommends that the newly established Commission on Organization of the Executive Branch of the Government, under the chairmanship of former President Herbert Hoover, be requested to consider the subject of dependent medical care, that the matter be thoroughly and exhaustively studied, and that the Congress be supplied with complete background and statistical information, as well as a discussion of the broad implications of the program, so that a sound national policy can be established.

Report of Reference Committee on Medical Military Affairs

Dr. William A. Hyland, Chairman, submitted the following report, which was adopted:

Resolution on "Doctor-Draft" Law: The report as presented by Dr. Murray states: The resolution on the "Doctor-Draft" law, introduced in June, 1953, by Dr. A. H. Aaron of New York, proposing that the recommendations of state and local Medical Advisory Committees to the Selective Service System be made mandatory rather than advisory, was considered by the Council on National Emergency Medical Service as directed by the House on recommendation of the Reference Committee on Legislation and Public Relations. It was the decision of the Council that its previous position be reaffirmed and that the proposal be not endorsed, and in this recommendation the Board of Trustees concurs. Experience has demonstrated that in the great majority of states the recommendations of the Medical Advisory Committees are accepted by state and local Selective Service boards. In addition, implementation of Dr. Aaron's proposal would require an amendment to the "Doctor-Draft" law. It is the opinion of the Board that such an amendment is neither necessary nor feasible at this time.

Your reference committee approves the decision of the Council, in which the Trustees concur, that the proposal be not endorsed owing to the fact that the implementation of Dr. Aaron's proposal would require an amendment to the "Doctor-Draft" law, it being the opinion of the Board that such an amendment is neither necessary nor feasible at this time.

Medical Policies in Disaster: Your committee recommends that the first sentence of the third paragraph be changed from "It is the recommendation of the Board of Trustees that the House of Delegates adopt a position in agreement with the statement of the American National Red Cross that the primary responsibility for the care of the sick and injured in disaster rests with the public health authority and local medl cal and allied professional organizations," to read: "It is th recommendation of the Board of Trustees that the House o Delegates adopt a position in agreement with the statemen of the American National Red Cross that the primary re sponsibility for the care of the sick and injured in disaste rests with local physicians and allied health personnel." It i further recommended that the first sentence of the fourtl paragraph become the last sentence of the third paragraph

Universal Military Training Program: The report, as rea by Dr. Murray, reads: "On Aug. 28, 1953, a statement pre pared by the Council on National Emergency Medical Serv ice and approved by the Board of Trustees was submitted t the National Security Training Commission. It is being pre sented to the House of Delegates at this time with the rec ommendation that the position recommended by the Associatio concerning the medical implications of a Universal Militar Training program may be affirmed. Affirmation of this stat ment does not in any way imply approval or disapproval c the establishment of a Universal Military Training program.

These medical implications referred to are: (1) The cor tinuation of preprofessional and professional education fc qualified students; (2) The performance of pre-induction, ir duction, and periodic reserve physical examinations; (3) Exter of medical services to be provided for members of the N tional Security Training Corps: (*a*) corrective treatment an rehabilitation, and (*b*) medical care during period of basi training; (4) Eligibility of members of National Security Trai ing Corps and Reserve components for veterans' medical ben fits; and (5) Source and selection of medical and allied pr fessional personnel.

Dependent Medical Care: Your committee recommends tl substitution of the word "method" for "practice" in the thi sentence of the second paragraph, and substitution of the wo "disadvantage" for "detriment" in the same sentence. Und (e) your committee recommends substitution of the wor "mechanism" for "principle."

Your reference committee wishes to emphasize with respe to this proposal that the policy advocated should not in an way be construed as one of opposition by the American Med cal Association to dependent medical care. As stated in th report, the recommendation is made that the Congress dete mine whether such care should be provided. The positio recommended refers only to the manner in which it should b provided if it is determined by the Congress to be a prope emolument of military service.

Report of Citizens' Advisory Commission on Medical Ca of Dependents of Military Personnel: Your committee recon mends deletion of the word "socialistic" in the last phrase c the second paragraph, and that in the middle of the fourt paragraph the word "generally" be substituted for "unive sally."

L. DONATION TO AMERICAN MEDICAL EDUCATION FOUNDATION

The Board contemplates another donation of $500,000 t the American Medical Education Foundation for the yea 1954. With this contribution the American Medical Assoc ation will have spent 2 million dollars for aid to the medica schools of the country. However, the Board wishes to call t the attention of the House that the financial status of th Association is such that a similar contribution cannot be con tinued indefinitely. Such an annual appropriation would soo become a matter of concern to the Board of Trustees in it effort to maintain a balanced budget. Consequently the Boar strongly urges the continued and increased support of medi cal schools by the individual physician and by organization in medical and allied fields.

M. REPORT OF COMMITTEE ON SPECIALISTS IN OTHER FIELDS

The Joint Committee of the Board of Trustees and the Council on Medical Education and Hospitals, appointed at the direction of the House of Delegates to study the relationship of American medicine to professional nonmedical groups in the health field, reported that it believes that the entire matter is of such importance that a small ad hoc committee will not do justice to the problem. The committee therefore recommended that (1) the Board of Trustees and the Council on Medical Education and Hospitals and its staff, in association with the appropriate councils and bureaus of the American Medical Association and relevant professional groups, undertake a detailed investigation of all facets of the problem and (2) following the receipt by the committee of a report from the Council on its findings and recommendations, the Committee on Specialists in Other Fields will submit a report of its recommendations to the Board of Trustees.

The Board concurs in the recommendations of the committee and requests the indulgence of the House of Delegates until a further report is received from the committee.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, submitted the following report, which was adopted:

Donation to the American Medical Education Foundation: The announcement by the Board of Trustees concerning the contemplation of another gift of $500,000 to the American Medical Education Foundation in 1954 is pleasing to note. Its warning that such annual gifts cannot continue indefinitely is most timely. It presents an added challenge to the medical profession as individuals to accept the obligation owed by each and every physician to the institution that has made his success in life possible. Without the instruction and training given to each of us by our respective medical schools at approximately one-third its cost, our station in life, our homes, and the benefits we give our children would not be possible. It is, therefore, a personal and family responsibility, not one for the profession at large. Doctors accept this challenge. This can be accomplished either by voluntary contributions or, if the constituent societies desire, by assessment. This latter method has been successfully demonstrated by the Illinois State Medical Society, whose membership should be complimented for their generosity.

Report of Committee on Specialists in Other Fields: The supplementary report of the Board of Trustees concerning specialists in nonmedical fields is simply informative and requires no action.

Messages Regarding Dr. George W. Kosmak and Dr. Charles H. Phifer

The Speaker announced that he had received a letter from Dr. George W. Kosmak regretting his inability, because of ill health, to attend the St. Louis Meeting, especially since this session would terminate his many years of service as delegate from the Medical Society of the State of New York.

It was also announced by the Speaker that Dr. Charles H. Phifer, delegate from the Illinois State Medical Society, and a member of the Council on Scientific Assembly, was unable to come to St. Louis because of illness.

The House of Delegates, by unanimous vote, instructed the Secretary to telegraph to Drs. Kosmak and Phifer the greetings and best wishes of the House.

Report and Supplementary Report of the American Medical Education Foundation

Dr. Louis H. Bauer, President, presented the report of the American Medical Education Foundation (see The Journal, Nov. 7, 1953, pages 956-957) and the following supplementary report, both of which were referred to the Reference Committee on Medical Education and Hospitals:

The report of the American Medical Education Foundation made to this House and printed in the Handbook of the House of Delegates was made as of July 1953. There have been some important changes in the status of the foundation since that report was rendered and for that reason this amended report is being made.

The income of the foundation now totals $1,000,174.00. This is worthy of note because it is the first time that the annual income has exceeded a million dollars since the inception of the foundation in 1950. This new total was made possible by the generous gift of the American College of Radiology, which renewed its support of this program with a gift of $2,000. Worthy of mention at this time also is the fact that the number of contributors to the foundation now exceeds the 1952 total by more than 200% (16,475 vs. 7,259 for 1952). The dollar amount received from individual contributors, mostly physicians, exceeds last year by approximately 50% and the gross total approximates a 15% increase over 1952. During the current year, with 65 of the 79 medical schools reporting their direct contributions, individual physicians in the United States have given $782,885 directly to their medical schools. This sum has been given by 22,273 individuals. At a regular meeting of the board of directors of the foundation the following were elected to serve as officers of the foundation or members of the board of directors: Dr. Louis H. Bauer, New York, was elected to the office of president, succeeding Dr. Elmer L. Henderson, deceased; Dr. George F. Lull was elected vice president, and Dr. Edward L. Turner, Secretary of the Council on Medical Education and Hospitals of the American Medical Association, was elected secretary-treasurer to fill the vacancy created by the resignation of Dr. Donald G. Anderson, dean, University of Rochester School of Medicine. Dr. Anderson, who served as secretary-treasurer of the foundation since its inception, was elected a member of the board of directors.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, submitted the following report, which was adopted:

Report of the American Medical Education Foundation: It is gratifying to note that the income of the American Medical Education Foundation now totals $1,000,174 and that the number of contributors to the foundation now exceeds the total for 1952 by more than 200% (16,475 vs. 7,259 for 1952). Likewise $782,885 has been given by individual physicians in the United States directly to their medical schools. In addition, recognition should be given to the American Medical Association for underwriting this foundation to the extent that every penny donated by a physician goes to a medical school.

Report of Judicial Council

Dr. Edward R. Cunniffe, Chairman, presented the following report of the Judicial Council, which was referred to the Reference Committee on Miscellaneous Business:

Since the interim meeting held in Denver in December, 1952, the Judicial Council has held four meetings divided into 14 sessions; 4 in conjunction with the annual meeting, 5 during the present clinical meeting, and the remainder at headquarters in Chicago. At these meetings routine business was transacted which included the recommendation of candidates for affiliate membership and consideration of many requests for decisions and opinions concerning ethical problems. In some instances, to insure prompt replies to inquirers, the Chairman of the Council gave personal, provisional opinions which were reviewed by the Council at subsequent meetings. Two appeals from decisions of constituent associations were heard by the Council. The following illustrate some of the questions which have been presented to the Council and the Council's action.

In the report of the Council submitted to the House of Delegates in December, 1952, it was stated that "the number of requests addressed to the Council for specific interpretations of the Principles of Medical Ethics continues to be ever increasing." This situation still prevails. The Council has no desire to avoid work which should legitimately come before it, but it has gained the impresison that many members of the Association do not fully grasp the real function of the Judicial Council in the proper administration of certain affairs of the Association. The Judicial Council is not an agency created to police the medical profession and enforce the Principles of Medical Ethics. The Bylaws of the Association vest in the Judicial Council the "judicial power" of the Association. This is authority to hear and determine issues presented to it but not to enforce or prosecute for violations.

It is true that the Council has jurisdiction over all matters of professional ethics, but this jurisdiction does not apply to the determination of the many ethical questions which often occur to the 140,000 or more members of the Association—it only applies to controversies. The Council was not created as a listening post for the purpose of airing discussions of abstract ethical problems. It is earnestly to be desired that individual members of the Association who question the ethics of some phase of their own or a colleague's practice should first submit their problems to the proper official body of their component medical society for a decision at the local level based on local custom and usage and local standards of practice. If this procedure is followed, only actual controversies will be presented to the Council and the proper work of the Council may be carried out more expeditiously.

Transfer of Membership

The Council has had numerous appeals from individuals regarding transfer of membership from one constituent association to another. Occasionally they have been unable to obtain membership in the component or constituent association to which they have applied for transfer despite the fact that they have been members in good standing of the American Medical Association. Many of these appeals have not been accompanied by all the information needed by the Council to enable it to render a decision. Some of the county and state organizations have failed to present complete membership data necessary for evaluation by the Council. This has resulted in the expenditure of unnecessary effort while obtaining facts pertaining to certain situations, and many times the Council has been unable to make a satisfactory decision due to the inadequacy of reports. These difficulties could be obviated if the county and state organizations would furnish a comprehensive summary of the membership activity of the applicant. This information would be of great value to the Council for many reasons. The prompt completion of this transfer is of vital importance to both the member and the American Medical Association, for if it is not completed in six months the applicant loses his membership in the American Medical Association and all the privileges attendant thereto. When a properly approved request for transfer is denied, the applicant can appeal to the Judicial Council. This privilege has been a tradition in our Association for many years.

Statement of Ownership of Pharmacy

The Council has had many inquiries regarding the ownership of pharmacies by physicians. The Principles of Medical Ethics are very clear in regard to this matter. Section 6, Chapter I of the Principles provides that "An ethical physician does not engage in barter or trade in the appliances, devices or remedies prescribed for patients, but limits the sources of his professional income to professional services rendered the patient." The Council has ruled that it is unethical for a physician to have a financial interest in a pharmacy in the area in which he conducts his professional activities and where he profits directly or indirectly from the sale of devices or remedies prescribed for his patients. This is particularly true when the services of other reputable pharmacies are readily available. Along with the problem of ownership of pharmacies by doctors may be considered the question of rental of space to a pharmacist in a clinic or office building owned or leased by physicians. When physicians rent such space on a sliding scale or for a percentage of the income received by the pharmacy the result is equivalent to receiving a rebate from the prescription and is therefore unethical.

The Purveyal of Medical Services

There have been many inquiries regarding the employment of physicians by hospitals. Most of them pertain to practices of anesthesiologists, radiologists, pathologists, and physiatrists.

The Council has repeatedly stated that the acceptance of a salary by a physician does not of itself constitute unethical conduct. This opinion is predicated on the Council's interpretation of the Principles of Medical Ethics, particularly Section 6, Article VI, Chapter III entitled, "Purveyal of Medical Services." It is the opinion of the Council that this section is a clear, unambiguous enunciation of a principle, and that ar uncertainty associated with the principle stems from failu to understand and appreciate that it must be applied to specific factual situation.

The issue to be resolved then is factual. If, in a given situ tion, a physician disposes of his professional services und terms which permit exploitation, his conduct is unethic Knowledge of the facts, however, may reveal that there is n exploitation; that there is not an unethical division of fe that there is not a denial of free choice of physician as d fined by the Principles or that the arrangement does not cau a deterioration of the quality of medical services.

The Judicial Council believes that the "Relation of Ph sicians and Hospitals" (Guides for Conduct of Physicians Relationships with Institutions) and the "Report of the Joi Committee on Hospital-Physician Relationships of the Boar of Trustees of the American Medical Association and Ame can Hospital Association" make it abundantly clear that wh such questions arise their solution depends on an analysis the factual situation which obtains in each relationship. Ea of these reports reaffirms in its own language existing ethi principles. Each suggests that solutions of controversies rel ing to financial arrangements can best be effected at the lo level. Each emphasizes that the question of ethics involv in establishing terms by which a physician may dispose his professional attainments or services depends on wheth they are exploited and whether any other principle of eth is involved.

Acceptance of Council Rulings

The Principles of Medical Ethics of the American Medi Association provides the basis on which are predicated principles of medical ethics, which are utilized to guide activities of physicians. The fact that a physician is a me ber of a specialty group or of a constituent association wh special interpretation of ethical principles has been provi does not release him from his obligation to comply with Principles of Medical Ethics of the American Medical As ciation. When classified special societies request a ruling the Council on behalf of their membership on the Princip of Medical Ethics, it is the duty of the membership of t particular society to accept the ruling of the Judicial Coun of the American Medical Association as final.

The Principles of Medical Ethics May Be Amended On by Vote of the House of Delegats of the American Medical Association

There have been instances in which a state association a specialty organization has announced an interpretation a segment of the Principles of Medical Ethics which is finitely contrary to that adopted by the American Medi Association. The Judicial Council wishes to emphasize that only method by which the Principles of Medical Ethics of American Medical Association may be altered requires formal presentation of a resolution to the House of Delega of the American Medical Association embodying an amer ment to the Principles of Medical Ethics. When the propos revisions are properly presented, they will receive appropri consideration and when reported by the reference committ will be subject to discussion and vote by the House of De gates. They may, however, be referred to the Council Constitution and Bylaws. The adoption and broadcasting so-called principles of medical ethics by any other proce by any other society or organization is to be condemne

Conclusion

In closing this report to the House of Delegates, your Jud cial Council solicits the most careful consideration by th members of the House and their constituency of 140,00 physicians to the loss of public confidence in the integrity the medical profession that follows each publicized expressi of personal opinion regarding unethical conduct alleged to currently prevalent in considerable segments of the natio We have the constitutional processes by which charges of u ethical conduct may be tried in an atmosphere of equity an fair play. Why not invite formal charges of misconduct amon members, and thereby insure each alleged offender trial by his peers rather than by sources that lead no further than to sensationalism and loss to our profession of the precious good will of the public?

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, presented the following report, which was adopted:

Report of the Judicial Council: Your committee reviewed the report of the Judicial Council and considered with great interest the various topics on transfer of membership, statement of ownership of pharmacy, the purveyal of medical services, and acceptance of council rulings. Your committee approves this report of the Judicial Council and recommends its adoption.

Report of the Council on Medical Education and Hospitals

Dr. H. G. Weiskotten, Chairman, presented the report of the Council on Medical Education and Hospitals (see THE JOURNAL, Nov. 7, 1953, pages 941-947), which was referred to the Reference Committee on Medical Education and Hospitals.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, submitted the following report, which was adopted:

Report of the Council on Medical Education and Hospitals: Your committee has carefully reviewed the report of the Council on Medical Education and Hospitals. Your committee wishes to call attention to that section of the report commenting on the National Commission on Accreditation. The Council is to be congratulated on keeping informed on this development and for its success in being formally recognized as one of the two agencies best fitted to establish standards and accredit programs in the field of medicine. It must be remembered that this does not close the issue.

It is further noted in the report that the Council recognizes the problem of evaluating the education and preparation of physicians who attended foreign medical schools and has informed your committee that it has instituted a continuing study of the problem.

In its report the Council has presented for approval by this House of Delegates two sets of essentials for technical schools. (1) Your reference committee has studied the "Essentials for the Training of Medical Record Technicians," which were temporarily approved by the House of Delegates in June, 1953. Your committee would like to point out that these essentials are incorrectly referred to as "Essentials for the Training of Medical Record Librarians" and should be referred to as "Essentials for the Training of Medical Record Technicians." With this correction, your reference committee recommends the approval of these essentials. (2) The Council also asks for approval of revised "Essentials of an Acceptable School of Medical Technology." Your reference committee has studied these revised essentials, has noted the alterations from the previous essentials, and recommends that the revised essentials be approved.

Your reference committee believes it desirable in this year's report to comment on the position which the Council on Medical Education and Hospitals occupies in the area of establishing and enforcing educational standards in medicine and related fields. Those who are not familiar with the history and traditions developed by the Council over a period of 50 years, with the support and encouragement of the House of Delegates, frequently assume that the Council's chief function is to protect the interests of the medical profession against any movements in medical education that physicians may feel are inimical to their personal interests. It is well known that the uninformed have often charged the American Medical Association with attempting through the activities of the Council to limit the number of physicians trained in this country. From time to time other less well-defined calumnies are advanced to support claims that the medical profession as such should have no voice in the establishment or enforcement of the educational standards. This attitude, which is unfortunately encountered too often, is potentially a dangerous one. The Council has recognized this danger and has constantly rededicated itself to the belief that it should at all times maintain maximum objectivity and that at all times in establishing and enforcing the standards it should be guided by the simple criterion of what is best for the public and what is best for medical education. Through the years the Council has striven, and your reference committee believes with success, to maintain this position even though it has at times brought serious criticism on the Council from small or large segments of the medical profession who fear personal inconvenience from the Council's actions. The Council has endured this criticism because it believes that the medical profession's legitimate interest and important influence in the maintenance of high standards of medical education can be preserved only so long as universities, medical schools, hospitals, and the general public have confidence that the profession's designated agency in educational matters, the Council, is free to devote itself to the support of sound principles of education and the welfare of society. It believes that the attainment of these objectives is also in the best interest of the welfare of the profession itself. Your reference committee feels certain that the House of Delegates appreciates the importance of this view and will support the Council in maintaining it.

A related problem that may be appropriately discussed at this time is the relationship of the Council's standards to the laws or regulations of individual states. On occasion in the recent past, the view has been advanced that the Council should not adopt any standards for the approval of institutions that are in conflict with the laws or regulations of any state. This is an untenable position. Its acceptance would mean that the Council could not raise standards above those of the state having the lowest standards. Approval by the Council is a voluntary, unofficial matter which must be requested by the individual institution. If an individual state imposes restrictions on a class of institution that will not permit them to meet the Council's standards, the institutions so affected have the choice of not seeking the Council's approval or working for a modification of the laws or regulations that prevent them from meeting the Council's standards. Your reference committee feels certain that it has the support of the House of Delegates on this fundamental issue because otherwise the Council would be powerless to have any influence on educational standards on a national basis.

The Council is also charged with the responsibility of inspecting and approving hospitals in their functions as agencies for graduate training. It is the belief of your reference committee that this activity directly improves the quality of medical service available to the public. Furthermore, it increases the effectiveness of the profession in its responsibility for the care and prevention of ill health.

Your reference committee recommends that the report of the Council on Medical Education and Hospitals be approved.

Report of Council on Scientific Assembly

Dr. Samuel P. Newman, member, presented for Dr. Henry R. Viets, Chairman, the following report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work:

To the Members of the House of Delegates of the American Medical Association:

Since the report given at the 1952 Clinical Meeting, the Council on Scientific Assembly met on Feb. 2, 1953, in New York, on May 31, 1953, also in New York, and on Oct. 19, 1953, in Chicago. Informal meetings were held in St. Louis on May 4 and on July 15 in Chicago, and the Council met with the Section Secretaries in Chicago on Oct. 20, 1953. The chairman also met with the officers of the Dade County

Medical Society in Miami, Nov. 11 and 12, for a preliminary consideration of the program for the Clinical Meeting to be held in Miami in December, 1954. The chairman also visited a number of medical schools in the South and Southwest for consultations with the deans and the faculty regarding the composition of the Miami program. The usual business was conducted at the various meetings of the Council with the principal emphasis being placed on program construction, integration with the activities of the Section Secretaries, a free interplay between the Council and the Committee on Scientific Exhibit and, in general, a drawing together of many divisions of the Scientific Assembly under the general guidance of the Council.

Denver Clinical Meeting

The Denver meeting was well attended; in some instances there were more persons at the General Assemblies than at the Annual Meeting in Chicago, held the previous June. The clinical presentations were also better attended than were some of the Section meetings in Chicago. The high rate of registration from Colorado and adjacent states, plus the enthusiasm shown by the physicians attending the individual sessions, gave sound evidence of the value of the Clinical Meeting to practitioners in areas of the country where the Annual Meeting could not be held because of limited accommodations. The Council is fully aware of the great educational opportunity provided by the Clinical Meetings and in building its programs quality has always been the first consideration both in the Assembly and in the exhibits. The Council would consider it appropriate to think in terms of regional areas rather than states when planning meetings in the future, lest the Clinical Meeting of the American Medical Association become a "glorified state meeting," rather than one embracing larger sections of the country, such as the Northwest, the Southwest, New England, etc. The Council noted with pleasure the activities of the Woman's Auxiliary in Denver and felt that their cooperation contributed greatly to the success of the meeting. It was suggested that this aspect of the Clinical Meeting might be more extensively developed at future meetings.

New York Annual Meeting

The meeting presented no unusual features as far as the program was concerned except the panel discussion in the General Scientific Meetings Friday morning on "Today's Medicine for Tomorrow's Patient." In spite of the large total registration, the audience was surprisingly small, again illustrating the difficulty of reaching a full attendance on the last day of the meeting even when an exceptional program is provided. The Section meetings in New York were fairly well attended. The upward trend in attendance noted in the last few years continued, although some of the Sections drew smaller numbers than in the past. No Section, however, fell to such a low level in attendance that its discontinuance was considered.

Future Meetings

Plans for the San Francisco Annual Meeting are well formulated. In most instances the Section Secretaries were able to report on a completed program when the Council met with them in an all day session in Chicago on Oct. 20, 1953. The Council suggested that a brief business meeting be held on the first day of the Section meetings, in addition to the regular business meeting on the second day, for the purpose of presenting resolutions which the Section may wish its delegates to introduce in the House of Delegates.

Reorganization Plan

Since January, 1948, when the first Clinical Meeting of the American Medical Association was inaugurated, the Council has been giving primary consideration to the preparation of programs for both the Annual and Clinical Meetings. Through the year 1953, including the St. Louis Meeting, 13 such programs have been arranged. Based on the experience of the Council during this period and after full consideration, e Council is now of the unanimous opinion that a reorganization plan should be considered at this time. The principal changes would be as follows:

1. The Council on Scientific Assembly should become a committee of the Board of Trustees, rather than a committee of the House of Delegates.
2. The Council on Scientific Assembly should incorporate into its structure the Committee on Scientific Exhibit.
3. A permanent office should be established at American Medical Association headquarters with a full-time secretary to carry on the activities of the Council as reorganized.
4. The Council should be enlarged from seven members to ten.
5. The Council on Scientific Assembly, constituted as above, would be able to set up separate committees on scientific exhibits, television, motion pictures and association exhibits, and a general program committee for both the Annual and Clinical Meetings.
6. The functions now carried on by the Council, other than arranging the programs, would be retained.
7. Report of the Council's activities would become part of the Report of the Board of Trustees and would still be subject to action by the House of Delegates.
8. The chief reason for reorganization is to aid in coordinating the functions of the Council with those of the Committee on Scientific Exhibit and other related components of the American Medical Association headquarters having to do with the Scientific Assembly.
9. If the plan is adopted, appropriate changes in the Bylaws will be necessary.

Miscellaneous

The Council voted to allot a Session on Legal Medicine and a Session on Allergy in the Section on Miscellaneous Topics for the San Francisco Annual Meeting. For the San Francisco Meeting, it was voted to revert to the former practice of holding the General Scientific Meetings all day on Monday and on Tuesday morning. The Section meetings will begin on Tuesday afternoon and continue through Friday morning.

The Council noted with regret the death of two former members, Drs. Frank H. Lahey and Alfred A. Walker. Dr. Lahey served the Council for ten years, from 1927 to 1937. Dr. Walker was a member from 1935 to 1945 and chairman from 1942 to 1945. Both contributed to the growth of the Council and brought the Scientific Assembly to a high standard through their devotion to the best interests of the American Medical Association.

Report of Reference Committee on Sections and Section Work

Dr. Jesse D. Hamer, Chairman, presented the following report, which was adopted:

The report of the Council on Scientific Assembly was reviewed by your committee, wherein it was noted with satisfaction the report submitted by this council concerning the quality of the programs displayed at the Denver Clinical Meeting last December and the New York Annual Meeting in June, 1953. It was noted also that plans are now well under way for the scientific program that will be presented in San Francisco next June and at the Miami Clinical Meeting in December, 1954.

Attention is called to this House by your committee to a consideration of the report of the Council on Scientific Assembly wherein a reorganization plan concerned with the Council and the Bureau of Exhibits is suggested. Your committee heard several representatives of both the Council on Scientific Assembly and the Bureau of Exhibits, all of whom expressed the desire that this reorganization plan begin the process of activation. No one appeared before your committee in opposition to this proposed plan.

Your committee recommends that the proposed reorganization plan affecting these two departments be accepted by this House in principle, and that it be referred to the Board of Trustees for further implementation.

Report of Council on Medical Service

Dr. Elmer Hess, Chairman, presented the report of the Council on Medical Service (see The Journal, Nov. 7, 1953, pages 947-955), which was referred to the Reference Committee on Insurance and Medical Service:

Supplementary Report of Council on Medical Service

Dr. Elmer Hess, Chairman, presented the following supplementary report of the Council on Medical Service, which also was referred to the Reference Committee on Insurance and Medical Service:

To the Members of the House of Delegates of the American Medical Association:

Following out the directives of the House of Delegates, which are found in the Council's report, the Council on Medical Service wishes at this time to submit the following supplemental report:

Four regional conferences concerning the policy of the American Medical Association with respect to veterans' medical care have been held by the Council's Committee on Federal Medical Services. These conferences, held in New York, Washington, Atlanta, and Dallas, were well attended by representatives of the 20 state medical associations invited.

The purposes of these conferences were: (1) to develop a working liaison with state association veterans' committees; (2) to discuss methods for carrying out the instructions of the House of Delegates; (3) to increase the number of physicians who have a working knowledge of the policy and the facts relating to it; and (4) to learn the situation in each state.

It is the consensus of the committee and the staff members attending these conferences that they were most successful in accomplishing the above listed purposes. In view of this, the Council recommends that, as soon as possible, similar regional conferences be held in those areas of the country not previously covered so that all states may be included. The Council further recommends that the House urge each state medical association to take formal action approving the policy statement on medical care for veterans with non-service-connected disabilities as adopted by the House in June, 1953. Finally, the Council recommends that it be authorized to develop liaison, through its Committee on Federal Medical Services, with national and local organizations interested in and concerned with veterans' medical care.

The Council would also like to take this opportunity to commend the chairman and members of the Committee on Federal Medical Services and the panel members participating in these conferences for the excellent manner in which they have been carrying out the directives of the House of Delegates.

Report of Reference Committee on Insurance and Medical Service

Dr. John M. Porter, Chairman, submitted the following report, which was adopted:

The work of the Council on Medical Service is of such tremendous scope and covers such varied fields that your committee and no doubt the House of Delegates has difficulty in appreciating all that has been done by the Council and its committees. Commendation and thanks are certainly in order to its chairman, its secretary, and all its members, who could not have accomplished what they have without tremendous sacrifice of time and effort. The work of the Council is reported in seven sections, corresponding to the actions taken by the different committees. Since there is some overlapping, the report of your reference committee will not follow these sections exactly.

In the matter of Extension of Hospitals and Other Facilities, your committee approves of all the actions reported. Continuation of the work on physician placement programs is especially important, with emphasis placed as it should be on what the community can do to attract new physicians, what the physician contemplating a change can do to adapt himself to a new community, and what organized medicine can do to get these two together and later to maintain the partnership by furnishing postgraduate education and other professional contacts.

Further stimulation of the formation and aggressive functioning of emergency call plans, grievance committees, and other community medical service programs is in order as planned by the Council. Your committee feels that the Council is right in assuming that the report of the Joint Committee on Hospital and Physician Relationships adopted in June, 1953, is supplemental to the report of December, 1951 on "Relationships of Physicians and Hospitals," but believes that it should be emphasized that the later document does not replace or repeal the first report.

It is obvious that the Committee on Indigent Care has given long and thoughtful consideration to that ever-recurring problem. Your reference committee recommends utilization of the "Guides for Evaluating Indigent Medical Care" wherever possible, but agrees with the statement that local problems will at times take precedence.

In the matter of maternal and child care, your committee feels that it cannot improve on the language of the Council report, and therefore quotes its recommendations and suggests your approval: "The only realistic approach to the problems encountered is . . . through local physicians, local hospitals and local agencies working . . . together to provide such care and services as are necessary." The Council recommends to the House of Delegates, and your reference committee approves, "That that portion of the report of the Citizens' Advisory Committee on Medical Care for Dependents of Military Personnel that has to do with maternal and child care be opposed, and that the Department of Defense be made aware of the work and conclusions of this Committee."

In regard to the request that the Los Angeles County Medical Association carry out the requests of the Council in the matter of a pilot study in maternal and child care and that the conclusions of this study be recommended to all county medical societies, your reference committee has taken no action, inasmuch as it understands the study is at present stalled for lack of funds.

The matter of medical care for industrial workers would seem to your committee to be a difficult problem in which many undesirable situations could easily arise. Comment before the committee in this regard would apparently justify the committee's apprehension. So far, union health centers, medical care of coal miners in isolated communities under the United Mine Workers' Welfare and Retirement Program, and similar innovations would seem to fit properly into the necessarily expanding care demanded by industrial groups. However, the opportunities for abuse of great sums of money by either management or the profession, possible extension of paternalistic schemes from areas where they might be necessary to larger urban centers where they would compete with existing medical facilities, and the tendency at times to ignore or override such fundamental concepts as free choice of physician are menacing possibilities. Your committee commends the Council for studies already made, in particular the conferences called in the soft coal areas, and recommends further careful study of this problem, keeping constantly in mind that the practice of medicine by groups and organizations under no circumstances frees the practitioner from adherence to the Principles of Medical Ethics, which guide the rest of us in our day-by-day professional contacts.

The Council reports continuing study of the presently unsatisfactory situation as regards professional liability insurance. Your committee recommends that this be continued and in view of the interim report presented by the Council recommends that no action be taken on Resolution No. 31 presented to this House Dec. 1 by Drs. Halley and Unfug, Colorado, which requested an investigation of this problem by the Board of Trustees.

Veterans medical services are referred to in the body of the Council report and again in the supplemental report presented to this House on Dec. 1. Your reference committee is in full agreement with the Council in its statement that the action of the House of Delegates in New York last June clearly stated its policy regarding treatment of non-service-connected disabilities by the Veterans' Administration. Unless and until that policy is changed by action of this House, the only problem remaining is how best to promote and gain support for this concept. Your reference committee feels that grass roots education of the public as outlined by the Council and as started in limited parts of the country is essential and should be expanded. Your committee feels that attention and effort in this regard is at present more urgent than attempts at direct legislative activity. The physician and the veteran are both voters and taxpayers, and certainly their best interests cannot be too far removed from one another. Education along this line is essential, and with it emphasis should be continued on the basic concept that only in this way can the best of care be furnished as it should be for those veterans with service-connected injuries or illness.

All of us can read with pride the latest figures on the expansion of voluntary prepayment health insurance. There is no need to quote the statistics furnished by the Council, because by the time that any totals can be published they have been exceeded. Nevertheless, certain fields have not yet been adequately covered, and vigilance and further work are essential. Numberless persons, many at state and local levels, share in the credit for the tremendous expansion of voluntary prepayment insurance. An essential part of this growth, however, has been the correlation and coordination furnished by the Council. Your committee commends the Council and recommends further stimulation along these lines, and also recommends adoption of Resolution No. 7, introduced by Dr. Baum for the Oregon State Medical Society.

The thanks of the committee are extended to those who attended the somewhat drawn-out hearings of the committee and the thanks of the chairman to those members of the committee who cooperated in the preparation of this report.

Report of Council on Constitution and Bylaws

Dr. Louis A. Buie, Chairman, presented the following report, and sections A, B, C, D, and E were referred to the Reference Committee on Amendments to the Constitution and Bylaws, and sections F and G to the Reference Committee on Miscellaneous Business.

To the Members of the House of Delegates of the American Medical Association:

A. The Council has considered several resolutions that were referred to it by the House of Delegates and reports as follows on each resolution:

(1) An amendment to Chapter IV, "Disciplinary Action," was offered by Dr. Joseph D. McCarthy, Nebraska, and, after amendment by the Reference Committee on Constitution and Bylaws, was adopted by the House of Delegates. This proposed amendment as adopted was referred to the Council on Constitution and Bylaws for implementation. The Council, in accordance with the action of the House of Delegates, has divided Chapter IV into 2 sections—Section 1 consisting of the present Chapter IV, and a new Section 2 which reads, "The Judicial Council, after due notice and hearing, may censure, suspend or expel any Service, Affiliate or Honorary Member of the Association for an infraction of the Constitution or these Bylaws, or for a violation of the Principles of Medical Ethics." In addition the Council has added titles to Sections 1 and 2, which read "Active and Associate Members" and "Service, Affiliate, and Honorary Members" respectively.

(2) A resolution on Seating of American Medical Association Delegates was introduced by Dr. John P. Culpepper Jr., Mississippi. This resolution sets forth provisions for the seating or unseating of delegates of constituent associations whose delegate representation was increased or decreaed by virtue of a change in American Medical Association membership within that constituent association. The reference committee, after consideration of the resolution, reported that "because of the different conditions in the several states and because the committee is of the opinion that each state should decide the manner of election of its delegates, this resolution should be referred to the Council on Constitution and Bylaws without recommendation." The Council, after study of this resolution, reached the same conclusion as the reference committee. Each constituent association should determine the method of selection of its delegates in a manner that does not conflict with the provisions of the Constitution and Bylaws of the American Medical Association. The Council, therefore, recommends that the resolution be not adopted.

(3) Dr. Russel V. Lee, Section on Military Medicine, presented the following Resolution on Revision of Principles of Medical Ethics:

> *Resolved*, To substitute for Chapter I, Sections 1 and 2 of the Principles of Medical Ethics the following section 1:
>
> We, physicians, affiliated with the American Medical Association, recognizing that, in common with physicians of the entire world, we are only trustees for the benefit of all mankind of the great treasure of medical knowledge and skill accumulated through the ages, accept with the trusteeship certain obligations as follows: (1) To make these benefits accessible to all who need them insofar as facilities permit; (2) to exercise these skills for the benefit of all humanity; (3) to strive constantly to improve ourselves in knowledge and skill; (4) to teach our art to all of good character who have the desire and capacity to learn insofar as proper means can be developed; (5) to increase by research and other means this share of knowledge and to make our discoveries freely available to all physicians; (6) to resist all attempts to misuse our services for political purposes, while freely discharging all our obligations as citizens; (7) to devote our skills to the alleviation of suffering and the deferment of death and never for any reason to the termination of human life; (8) to aid and support our medical colleagues in all countries in the attainment of proper humanitarian objectives; (9) to maintain in our relationships with our patients, our colleagues, and the public the strictest standard of personal honor, and (10) to dedicate our knowledge and skills and our lives to the alleviation of suffering, the prolongation of life, and the enrichment of living for all men without thought of any personal advantage or gain.

The reference committee recommended referral of the resolution to the Council on Constitution and Bylaws for its consideration in the forthcoming revision of the Principles of Medical Ethics. The Council has carefully considered this proposed amendment of the Principles of Medical Ethics but has deferred final action pending the consideration of amendments to other sections of the Principles of Medical Ethics which, in the opinion of the Council, are more urgent at this time. The Council, in its revision of the Principles of Medical Ethics, has adopted the policy of proceeding slowly and of giving its attention to those sections which have been most controversial and to the format of the Principles. The revisions suggested by the Lee resolution do not constitute any fundamental change in the existing Principles but are primarily a rewording and restatement of Sections 1 and 2. When the Council has completed other portions of the Principles, it will give further consideration to this resolution. The Council, therefore, recommends that action on the resolution be postponed.

(4) Two resolutions on (*a*) Principles of Medical Ethics, and (*b*) Clarification of Section 5 of Principles of Medical Ethics were introduced by Drs. Harlan English, Illinois, and Millard D. Hill, North Carolina, respectively. These resolutions refer to one of the most controversial sections of the Principles and request the Council on Constitution and Bylaws to outline in specific terms billing procedures when two or more physicians render medical service to a single patient.

After exhaustive consideration of the problem, the Council recommends to the House of Delegates that revision of Section 5, Article VI, Chapter III, be deferred until the constituent associations have had an opportunity to study a questionnaire and report to the Council the billing procedures that are approved in their respective areas. The Council believes that the nature of this subject is so vital that any action taken by this House of Delegates should clearly reflect the prevailing opinions of the constituent associations. The Council proposes to conduct a questionnaire survey of the constituent associations to determine their official policies on this matter, after which it will report its findings to the House of Delegates. The Council recommends that the House endorse its decision to postpone action until this survey has been completed. It also requests that the House urge the constituent associations to give their special attention to this survey.

(5) Resolutions on Membership in the American Medical Association Sections were introduced by Dr. R. J. Azzari, New York, as follows:

> *Resolved*, That the method of enrolling as members of the several sections be altered so that a member will indicate his specialty membership preference at the time of paying his American Medical Association dues, instead of being required, as at present, to be present at the annual meeting; and be it further
>
> *Resolved*, That the Secretary of the American Medical Association cause to be prepared rosters showing the names of those who have indicated their desire to become members of the several sections, and these lists so prepared shall constitute the membership rolls of the several sections so long as these members remain in good standing.

The reference committee, in conference with the Secretary of the Association, approved the resolution, and it was adopted by the House of Delegates. It was referred to the Council on Constitution and Bylaws for implementation, since it requires an amendment of the Bylaws, Division Two, Chapter V, Sec. 1 (A). The Council recommends that this resolution be reconsidered by the House of Delegates, since it was introduced as a simple resolution and should have been introduced as a resolution to amend the Bylaws, and, furthermore, the implications of the resolutions are so far-reaching that the Reference Committee on Amendments to the Constitution and Bylaws of this House of Delegates should be given an opportunity to reevaluate their impact with the assistance of the Secretary and members of this Council. It is the opinion of the Council on Constitution and Bylaws that the American Medical Association is divided into sections mainly for the purpose of providing registration at the Scientific Assembly and not to establish autonomous professional societies within the Association.

B. The recommendation has been made to the Council on Constitution and Bylaws by the Secretary and General Manager and the Speaker of the House of Delegates that the Reference Committees on Hygiene and Public Health and Industrial Health be combined, since the number of resolutions referred to each reference committee rarely is sufficient in number to warrant a separate committee and since the subject matter overlaps to a certain extent. The Council concurs in this recommendation and recommends that Chapter XII, Section 4 of the Bylaws be amended as follows to provide this change.

(1) Subsection (F), Section 4, Chapter XII, revise this subsection to read, "(F) Hygiene and Public Health and Industrial Health to which shall be referred all matters relating to hygiene and public health and all matters relating to workmen's compensation and those phases of medical care, including rehabilitation and public health administration, which affect the worker";

(2) Subsection (J), Section 4, Chapter XII, delete the entire subsection.

(3) Subsection (K), Section 4, Chapter XII, shall become Subsection (J) without any change.

(4) Subsection (L), Section 4, Chapter XII, shall become Subsection (K) without any change.

(5) Subsection (M), Section 4, Chapter XII, shall become Subsection (L) without any change.

(6) Subsection (N), Section 4, Chapter XII, shall become Subsection (M) without any change.

C. The Director of the Department of Records and Circulation recommended to the Council that the Bylaws be amended by adding to Chapter III, Section 5, the sentence, "Members of the American Medical Association who have been dropped from the membership roll for nonpayment of annual dues can not be reinstated until such indebtedness has been discharged, but such indebtedness shall apply only to the one year of delinquency." The Council concurs in this recommendation and recommends that the amendment be adopted by the House of Delegates.

D. Review of Sections 1 and 2, Chapter VIII of the Bylaws, reveals that the term "Editor of The Journal" appears in several places. The Council recommends that for the sake of clarity the word "Editor" be used, and that the words "of The Journal" be deleted from the 7th line of Section 1, Chapter VIII, and from the last line of Section 2, Chapter VIII.

E. The Council wishes to call the attention of the House of Delegates to an excellent article entitled "Development of Uniformity in Membership Regulations Between Constituent Associations and the A. M. A." which appeared in the Nov. 28, 1953, issue of THE JOURNAL. The Council believes that every constituent and component medical society should give this article special attention and attempt to implement the recommendations made therein so that membership requirements in the component societies can be made more uniform.

F. Principles of Medical Ethics: The Council recommends that the format of the Principles be changed so that a consistent terminology is used throughout in identifying the various chapters, sections, and paragraphs. To accomplish this uniform identification, the Council recommends the following changes:

(A) 1. All chapters shall be designated by Roman numerals.
    2. All sections shall be designated by Arabic numerals.
(B) 1. Delete the designation "Article I" so that the four sections of this article compose the entire Chapter III.
    2. Delete "Article II" and substitute "Chapter IV", so that this chapter will contain three sections.
    3. Delete "Article III" and substitute "Chapter V," which will contain eight sections.
    4. Delete "Article IV" and substitute "Chapter VI" and delete "Article V," which becomes Section 9 of Chapter VI.
    5. Delete "Article VI" and substitute "Chapter VII," which contains six sections.
(C) 1. Delete "Chapter IV" and substitute "Chapter VIII," which contains three sections.

The changes enumerated under (B) 1 to 5, provide for the elimination of the word "Article" from the Principles of Medical Ethics and the substitution of the word "Chapter" so that the Principles, after these changes are made, will contain chapters and sections throughout.

G. The Council has given special attention to Section 5, "Educational Information Not Advertising." It recommends that the second paragraph, which refers to advertising, be transferred to Section 4, where it becomes the second paragraph. The Council recommends that the title of Section 5 be changed from "Educational Information Not Advertising" to "The Relationship of the Physician to Media of Public Information," and that the following revised Chapter I, Section 5 by approved by the House of Delegates:

THE RELATIONSHIP OF THE PHYSICIAN TO MEDIA OF PUBLIC INFORMATION

Many people, literate and well educated, do not possess a special knowledge of medicine. Medical books and journals are not always easily accessible or readily understandable.

The medical profession considers it ethical for a physician to meet the request of a component or constituent medical society to write, act or speak for general readers or audiences. On the other hand, it may often happen that the representatives of popular news media are the first to perceive the adaptability of medical material for presentation to the public. In such a situation the physician may be asked to release to the public some information, exhibit, drawing or photograph. Refusal to release this material may be considered a refusal to perform a public service, yet compliance may bring the charge of self-seeking or solicitation.

An ethical physician may provide appropriate information regarding important medical and public health matters which have been discussed during open medical meetings or in technical papers which have been published, and he may reveal information regarding a patient's physical condition if the patient gives his permission, but he should seek the guidance of appropriate officials and designated spokesmen of component or constituent medical societies. Spokesmen should be empowered to give prompt and authoritative replies and a list should be issued which identifies them and discloses the manner in which they may be reached. These provisions are made with full knowledge that the primary responsibility of the physician is the welfare of his patient but proper observation of these ethical provisions by the physician concerned should protect him from any charge of self-aggrandizement.

Scientific articles written concerning hospitals, clinics or laboratories which portray clinical facts and technics and which display appropriate illustrations may well have the commendable effect of inspiring public confidence in the procedure described. Articles should be prepared authoritatively and should utilize information supplied by the physician or physicians in charge with the sanction of appropriate associates.

When any sort of medical information is released to the public, the promise of radical cures or boasting of cures or of extraordinary skill or success is unethical.

An institution may use means, approved by the medical profession in its own locality, to inform the public of its address and the special class, if any, of patients accommodated.

Report of Reference Committee on Amendments to the Constitution and Bylaws

Dr. William L. Benedict, Chairman, submitted the following report, which was adopted and the Resolutions on Membership in American Medical Association Sections, referred to in paragraph A(5) of the report of the Council on Constitution and Bylaws, rescinded:

Your committee has carefully considered the report of the Council on Constitution and Bylaws presented by the Chairman, Dr. L. A. Buie. In reference to A(1) of this report your committee approves the action of the Council relative to Chapter IV of the Bylaws entitled "Disciplinary Action" and recommends adoption of this portion of the report.

A(2) A resolution on seating of American Medical Association Delegates was introduced in June, 1953, by Dr. John P. Culpepper Jr. of Mississippi. Your committee approves the recommendation of the Council that the resolution be not adopted.

A(3) A resolution introduced by Dr. Russel V. Lee proposed specific amendments to the Principles of Medical Ethics. This committee approves the action of the Council in recommending that action on the resolution be postponed.

A(4) The Council recommends that the House endorse its decision to postpone action on these resolutions until a survey of the constituent associations be completed and requests that the House urge the constituent associations to give their special attention to this survey. Your committee commends the Council on its decision and recommends the adoption of this portion of their report.

A(5) This resolution adopted by the House of Delegates in June, 1953, was referred to the Council on Constitution and Bylaws for implementation, since it requires an amendment of the Bylaws, Division Two, Chapter V, Sec. 1(A). Your committee has information that the objectives of the sponsors of this resolution adopted by the House in June, 1953, have been attained by other means. Your committee concurs in the request of the Council that this resolution be reconsidered by the House of Delegates.

(B) Your committee concurs in the recommendation of the Council with the substitution of a comma for "and" after "Hygiene."

(C) Your committee approves the recommendation of the Council on the proposed amendment with the addition to the recommended sentence of the words, "provided that the year 1950 shall not constitute the year of indebtness," so that this amendment will read: "Members of the American Medical Association who have been dropped from the membership roll for nonpayment of annual dues cannot be reinstated until such indebtedness has been discharged, but such indebtedness shall apply only to the one year of delinquency, provided that the year 1950 shall not constitute a year of indebtedness."

(D) This committee approves and recommends the adoption of Section D of the report.

(E) Your committee approves and recommends the adoption of Section E of the report.

Your reference committee desires to express its heartiest commendation to the council on Constitution and Bylaws for its outstanding service to the Association, and to the members of the Council individually and collectively our sincere appreciation of their accomplishments, and to pledge our support to their efforts to so construct the Constitution and Bylaws that they may best guide our members in the conduct of their professional lives.

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, submitted the following report, which was adopted:

Report of the Council on Constitution and Bylaws: The Reference Committee on Miscellaneous Business received sections F and G of the report of the Council on Constitution and Bylaws for its consideration. In section F the Council recommends that the format of the Principles of Medical Ethics be changed so that a consistent terminology is used throughout in identifying the various chapters, sections, and paragraphs. The recommendations to accomplish this are approved. In Section G the Council recommends that the title of Section 5 be changed from "Educational Information Not Advertising" to "The Relationship of the Physician to Media of Public Information," and that Section 5 be revised as submitted in the report. Your committee approves these recommendations and recommends the approval of these sections of the report.

Report of the Committee on Blood

Dr. L. W. Larson, Chairman, presented the following report, which was referred to the Reference Committee on Miscellaneous Business:

Defense Blood Requirements: The end of the Korean hostilities resulted in a sharp downward drop in defense blood requirements. Since June 30, 1953, on advice of the Office of Defense Mobilization, the American National Red Cross has closed all of its 15 defense centers and terminated contracts with all of the 33 participating private blood banks which supplied blood for defense use. At present, defense blood collections are made only in regions served by the 45 regional Red Cross centers. The community blood banks have been required to make onerous reorganizations of their personnel and programs as a result of the cancellation of their defense contracts. A public relations problem also has been created since the public and the profession experience difficulty in understanding the continued public appeals for defense blood in the face of the withdrawal of organized defense collections in many areas of the country. It is hoped that the geographic inequities presently existent in the defense collection of blood may be averted by future agreements so that donors in all parts of the country may have the privilege of aiding the defense effort. In recognition of the public relations problem, the Office of Defense Mobilization has invited representatives of the American Medical Association and the American Association of Blood Banks to membership on its publicity policy committee.

Gamma Globulin: In the June report of the Committee on Blood, the composition of the national pool of gamma globulin and its method of allocation and distribution under the Office of Defense Mobilization was described. The actual task of distribution was delegated to the Division of Civilian Health Requirements of the United States Public Health Service. It will be recalled that the plan contemplated distribution of three allocations of poliomyelitis immune globulin. The basic allotment was made available on May 15 on request of state or territorial health officers.

On the basis of an increased incidence of poliomyelitis, 23 areas requested and received additional allocations, and in 14 areas supplementary gamma globulin was made available for mass prophylaxis. Thus from May 15 to Sept. 30, 1953, 1,715,000 cc. of gamma globulin was distributed under basic allocation; 436,344 cc. was made available as an additional allocation; 1,588,930 cc. was utilized in mass prophylaxis; and 32,402 cc. was used for research and special allocations. Of the total of 3,772,676 cc. thus distributed, 1,207,600 cc. was supplied to the pool by the National Foundation for Infantile Paralysis. The remaining 2,565,076 cc. was supplied by the American National Red Cross. In July, the Surgeon General of the United States Public Health Service organized a committee of practicing physicians to advise the service on practical problems encountered by practicing physicians in the explanation and the operation of the distribution system. Taken from the over-all viewpoint, the plan seems to have operated fairly smoothly. Initially, there were occasional difficulties in securing gamma globulin for measles prophylaxis. This resulted from misunderstanding on the part of a few local health officers that measles and infectious hepatitis should be given priority of use of gamma globulin.

If the incidence of poliomyelitis continues on the same level as indicated for the period May 15 to Sept. 30, 1953, it is anticipated that the pool will have a surplus of gamma globulin to carry over for use in the year 1954.

Progress Report on National Blood Program: The House of Delegates in the June, 1953, session adopted a Resolution on Blood Banking which urged "the establishment of a coordinated national blood bank program organized by the American Medical Association, the American National Red Cross and other qualified organizations interested in blood banking in so far as may be appropriate. . . ." The House also approved a request of the Committee on Blood that the committee be authorized to take part in conferences on a national blood program with the interested agencies.

Pursuant to these instructions, four meetings were arranged. The first, on July 25, 1953, in Chicago with representatives from the American National Red Cross, developed broad general areas of agreement on the necessity for a coordinated national blood program and an agreement that other professional organizations should be included in further conversations.

At the second meeting, in Washington on Sept. 9, the American Hospital Association, the American Association of Blood Banks, and the American Society of Clinical Pathologists were invited to attend. Each organization was represented by two appointees and the American National Red Cross and the American Medical Association by four appointees, with the chairman of the Committee on Blood presiding.

Representatives of all the organizations present expressed the belief that a voluntary national organization with representation from all agencies interested in blood collection, preservation, and distribution was desirable. In order to present some concrete recommendations to each organization's policy making bodies, the representatives at this meeting requested the chairman to appoint a steering committee of five members representing all the organizations present for the purpose of formulating a general plan of organization on the following basis: (1) to coordinate activities of member groups; (2) to recommend pertinent policy to constituent members on the national level; and (3) to explore further fields of activity into which the program should advisedly enter.

The steering committee was instructed to have this plan of organization ready for presentation to the joint committee on Nov. 13, in Washington. The steering committee met in Chicago on Oct. 21, and devised an organizational plan which was further discussed and amended by the representatives of the aforementioned agencies in the Nov. 13 meeting. As none of the representatives could pledge their organization's support of the plan, it was agreed that the plan should be submitted to each organization's policy making bodies for ratification, modification, or rejection. A copy of the plan of organization of the National Blood Foundation has been distributed to each member of the House of Delegates for purposes of information.

The board of governors of the American National Red Cross on Nov. 16, 1953, adopted the following resolution after considering the contemplated plan of organization of the National Blood Foundation:

> That the Board of Governors approve in principle the formation of an organization comprised of representatives from agencies interested in activities related to the collection, processing, and use of blood and its derivatives, with the understanding that the purpose of this organization shall be to establish a national blood program with a principal objective of assuring an adequate supply of blood and blood derivatives for civilian and military use in time of peace and for emergency without charge for the product itself. It is further recommended that the president or his designee be authorized to commit funds of the Red Cross on a cooperative basis with the American Medical Association and to the extent necessary during the next three years to effect and sustain such an organization and that the staff be directed to continue to plan with the other interested agencies with a view toward the development of a comprehensive plan to be submitted to the Board of Governors for subsequent action.

Since the plan of organization of the National Blood Foundation requires the assumption of certain financial obligations on the part of the American Medical Association, the Committee on Blood has presented the plan to the Board of Trustees for its consideration and for its recommendations to the House of Delegates.

Supplementary Report of Board of Trustees

Dr. L. W. Larson, Trustee, presented the following supplementary report, which also was referred to the Reference Committee on Miscellaneous Business:

O. Progress Report on the National Blood Program

In reviewing the plan of organization of the proposed National Blood Foundation, referred to the Board of Trustees by the Committee on Blood, the Board felt that approval in principle of the establishment of a national blood program has already been achieved by approval of the Resolution on Blood Banking at the June, 1953, meeting of the House of Delegates.

The Board of Trustees has not had complete opportunity to evaluate the financial and legal obligations to be assumed by the American Medical Association in the proposed organization. For the reasons stated, the Board of Trustees recommends that the Committee on Blood be instructed to continue its efforts, in cooperation with the other interested agencies, toward the development of an organization which will command the endorsement and support of the agencies concerned and incorporate the sound principles already enunciated by the House of Delegates.

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, submitted the following report, which was adopted.

Report of Committee on Blood and Supplementary Report of Board of Trustees on the Progress Report on the National Blood Program: Your committee reviewed with interest the report of the Committee on Blood and viewed with satisfaction its continued attempts to develop a comprehensive plan on a nationwide basis. In the supplementary report concerning the organization of the proposed "National Blood Foundation," the Board of Trustees felt that approval in principle of the establishment of a national blood program has already been achieved by the approval of the Resolution on Blood Banking at the June, 1953, meeting of the House of Delegates, which reverts to the Ludwig resolution. The Board of Trustees stated in this report that it had not had complete opportunity to evaluate the financial and legal obligations to be assumed by the American Medical Association in the proposed organization. For the reasons stated, the Board of Trustees recommended that the Committee on Blood be instructed to continue its efforts, in cooperation with other interested agencies, toward the development of an organization which will command the endorsement and support of the agencies concerned and incorporate the sound principles already enunciated by the House of Delegates.

Your committee approves the report of the Committee on Blood and the recommendations of the Board of Trustees in its supplementary report.

Introduction of Secretary of Southern Medical Association Mr. C. P. Loranz

The Speaker introduced to the House of Delegates Mr. C. P. Loranz, Secretary of the Southern Medical Association for more than 40 years.

New Business

The Speaker announced a new procedure for the presentation of resolutions, as follows:

Instead of having a roll call by states, as we have had in the past for the introduction of resolutions, in order to make your work easier, the resolutions have been numbered. You will notice that in the supplementary reports of the Board of Trustees letters were used. The resolutions are designated by number. I am going to ask the introducers of resolutions please to keep track of the numbers, and I am going to ask Nos. 1, 2, 3, 4, and 5 to come up here and sit at the table. No. 1 will be the first to be called, and, as each man moves up, another one will come up, so that we shall keep these five chairs filled at all times. If you have a resolution to be introduced, you will know when you are going to be called by the number that is on your resolution.

No. 1. Resolutions on Ethical Advertising

Dr. Frank J. Holroyd, West Virginia, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

The following resolution was unanimously adopted by the House of Delegates of the West Virginia State Medical Association at the second session held at the Greenbrier, White Sulphur Springs, July 24, 1953:

> Whereas, The advertising of therapeutic agents in the official journals of the American Medical Association and the promotion of Council-approved medications by this and all other means are of incalculable importance in influencing their use by medical practitioners; and
>
> Whereas, The advertising in many other journals, national and state, takes its tone from the official journals of the American Medical Association; and
>
> Whereas, Claims as to therapeutic advantages and disadvantages can be so devised as to give a total impression different from that which is justified; therefore be it
>
> *Resolved*, That the West Virginia State Medical Association urges the House of Delegates and the Board of Trustees of the American Medical Association to give consideration to measures which will insure complete conformity of all therapeutic claims with those recognized by the appropriate official authorities of the American Medical Association, and further, that steps be taken to strengthen the facilities for the detection and evaluation of all toxic reactions to therapeutic agents; and be it further
>
> *Resolved*, That the delegates of the West Virginia State Medical Association are hereby instructed to introduce this resolution to the House of Delegates at the Clinical Meeting in St. Louis in December, 1953.

Report of Reference Committee on Hygiene and Public Health

The Reference Committee on Hygiene and Public Health included its action with respect to the foregoing Resolutions on Ethical Advertising in its report on Supplementary Report of the Board of Trustees G. This will be found on page 1539 of this issue of THE JOURNAL.

No. 2. Resolutions on Principles of Medical Ethics

Dr. George Braunlich, Iowa, introduced the following resolutions which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The prime objective of the medical profession is to render service to humanity, with reward or financial gain a subordinate consideration; yet

WHEREAS, The matter of fees, collections, and statements must be covered; and

WHEREAS, The decision as to the ethical or unethical nature of practice must be based on the ultimate effect for good or ill on the patient as an individual and the public as a whole; and

WHEREAS, With the increasing development of medical knowledge and the increasing specialization of medical skill, it has become more and more frequently necessary for two or more physicians to participate in the care of a patient; and

WHEREAS, It is also a known fact that for the welfare of the patient, two or more doctors must be present at surgery in the event of the disability of any one of them during the operation or in an emergency, and this is a requirement in many hospitals' rules and regulations; and

WHEREAS, In many communities in Iowa, it has been common practice for the general practitioner or family physician and/or another physician to participate in the medical and surgical care of the patient, the family or patient in many instances requesting the family physician to be present at surgery and to assist in the care of the patient; and

WHEREAS, It has been accepted and approved by the community as a community practice conveying definite benefits to the community, and the procedure has received community approval as being in the best interest of the patient; and

WHEREAS, The above practice is generally recognized throughout the State of Iowa in both large and small communities; and

WHEREAS, The patients and the public have accepted and approved the joint activities of doctors of medicine on individual cases, in cases involving surgery, or in cases involving diagnosis and treatment only, all to the benefit of the patient; and

WHEREAS, In many communities there have been joint activities by doctors of medicine and one bill rendered therefor with the consent of the patient; and

WHEREAS, Physicians and surgeons have, in their activities of rendering joint services to the patient with the patient's consent, collected the fee on one statement and have thereby fulfilled their plain and palpable duty to their fellow men and have had due regard to all of the circumstances of each particular situation and relations; and

WHEREAS, In many instances patients have expressed their own desire for one bill, the payment of the bill at one place, and so by custom made the practice an accepted one in many communities; and

WHEREAS, Public policy is the community common sense and common conscience extended and applied throughout the state to matters of public morals, public health, public safety, public welfare, and the like; now therefore be it

Resolved, That when two or more doctors actually and in person render service to one patient, each physician may, if he so desires, render to the patient an individual bill for his individual services or the doctors may submit one statement to the patient for the services rendered, and it should be made clear to the patient or his legal representative that this fee is to be divided in proportion to the services rendered, and the statement shall show the names of the doctors and respective amounts to be paid each doctor. The patient's consent, either expressed or implied, should be obtained. The fees may be paid in their entirety to either physician by the patient, and the one receiving payment shall forward the other his fee. Under no circumstances shall it be considered ethical for doctors to submit joint bills unless both have actually rendered service. Division of fees for referrals only shall be considered unethical; and be it further

Resolved, That in legal partnerships of doctors, or clinics of doctors, or where doctors have joined together in the practice of medicine, and so hold themselves out to the public and patients, where all income and expenses are a joint account or joint venture, it is ethical and legal for the members of the group to confer and care for a patient and to render one bill to the patient, and the income shall be divided in accordance with their contract basis or salary or percentage arrangement.

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, presented the following report, which was adopted:

Resolution No. 2 on the Principles of Medical Ethics: Those resolutions were passed by the house of delegates of the Iowa State Medical Society in June, 1953. After thorough discussion of the problems involved concerning the billing of patients, your committee feels that it is unable to render a decision because the final interpretation of ethics is within the province of the Judicial Council. We note in the minutes of the House of Delegates at its December, 1952, meeting in Denver that the Judicial Council rendered an opinion on an almost identical question. On page 1706 of THE JOURNAL in the Dec. 27, 1952, issue is found this statement: "That when a surgeon renders his bill for his fee, it should not includ bills from colleagues who act as assistants or anesthetist but these colleagues should render their own bills."

Your committee recommends that these resolutions be referred to the Judicial Council requesting that the Council investigate the factors involved in the matters as presented an determine if there are new factors or new facets that woul cause it to change the opinion of 1952 quoted above. In addition we recommend that the Judicial Council be specificall requested to report on this request at the June 1954 annu meeting. We further recommend that this action be approve by the House of Delegates.

No. 3. Resolution on Chiropractic and Naturopathic Education

Dr. J. Paul Jones, Alabama, introduced the following res lution, which was referred to the Reference Committee o Hygiene and Public Health:

WHEREAS, The medical profession is morally, and in some instanc legally, obligated to protect the public against irregular practitioners all types; and

WHEREAS, Chiropractors and naturopaths are constantly trying to clo themselves with unwarranted status by means of legislative action; and

WHEREAS, Although we know the basic tenets of both chiropractic a naturopathy to be without scientific basis, the argument most readi understandable to a legislator seems to lie within the lack of prop training received in chiropractic or naturopathic schools; and

WHEREAS, When appearing before a legislative committee for the purpo of a hearing, we do not have and therefore cannot use concrete eviden regarding the quality of training received in either chiropractic naturopathic schools; and

WHEREAS, This situation resolves itself into the word of one gro against that of another, which in turn makes our strongest point—the la of proper training—the weakest link in our argument; therefore be it

Resolved, That the American Medical Association, through its prop council, institute means and procure accurate and concrete evidence the quantity and quality of training received in chiropractic a naturopathic schools; and be it further

Resolved, That the American Medical Association make this informati available to the constituent state associations not later than Jan. 1, 1955.

Report of Reference Committee on Hygiene and Public Health

Dr. Thurman B. Givan, New York, Chairman, present the following report, which was adopted:

Res. No. 3 on Chiropractic and Naturopathic Educatio Your committee approves this resolution and recommends th the American Medical Association, through its Board of Tru tees, by means of a proper council or an outside agency, i stitute methods and procure accurate and concrete eviden on the quantity and quality of training received in chiropract and naturopathic schools, and it is further recommended th the American Medical Association make this informatio available to the constituent state associations at the earlie possible date.

No. 4. Resolution on Use of Term Rehabilitation

Dr. Edward L. Compere, Section on Orthopedic Surger introduced the following resolutions, Nos. 4, 5, 6, and 6- all of which were referred to the Reference Committee o Sections and Section Work:

WHEREAS, Rehabilitation is the concern not alone of one group physicians but rather the concern of physicians in every branch of med cine, the present tendency for one group of physicians to arrogate t term "rehabilitation" unto themselves cannot be justified; and

WHEREAS, Orthopedic surgery is particularly concerned with this matt and from its inception as a specialty has always had the rehabilitation the physically disabled as one of its primary activities and has contribut and is contributing much to the development of this field; and

WHEREAS, The term "rehabilitation" has been appended to the title one of the official councils, the council designated as the Council o Physical Medicine and Rehabilitation; to one of the scientific sections, th Section on Physical Medicine and Rehabilitation; and to a specialty boar the American Board of Physical Medicine and Rehabilitation; and

WHEREAS, It is our firm belief and conviction that such use of thi term is inappropriate and misleading and causes confusion in the mind of the medical profession and the public at large; therefore be it

Resolved, That the House of Delegates advise the Council on Physica Medicine and Rehabilitation, the Section on Physical Medicine and Re habilitation, and the American Board of Physical Medicine and Rehabili tation that it would be desirable and appropriate to discontinue the u of the term "rehabilitation" in the title.

No. 5. Resolution on Advisory Committee to Council on Medical Education and Hospitals

WHEREAS, We believe that it is inappropriate for a subcommittee from the Council on Physical Medicine and Rehabilitation to serve in an advisory capacity to the Council on Medical Education and Hospitals regarding the educational standards of schools of physical therapy and occupational therapy, because the training of these technicians involves the services of many other fields of medicine, and advisory committees should consist of a much broader group; and

WHEREAS, Physical therapy and occupational therapy were developed with the encouragement and under the auspices of orthopedic surgery; and

WHEREAS, The education of physical therapy technicians and occupational therapists from the beginning was guided by orthopedic surgeons; and

WHEREAS, It is only proper that orthopedic surgery should continue as a participant in maintaining the standards of education and the rules of activity of physical therapy and occupational therapy; therefore be it

Resolved, That this advisory committee to the Council on Medical Education and Hospitals be selected from nominees submitted by the executive committees of the Sections on Physical Medicine, Orthopedic Surgery, Nervous and Mental Diseases, General Practice, and other sections which are concerned with the question of the training and education of lay technicians.

No. 6. Resolution on Change in Name of Council on Physical Medicine and Rehabilitation

WHEREAS, We do unanimously hold that it is not advisable to designate a council which was created for the purpose of evaluating and making recommendations regarding medical equipment and apparatus as the Council on Physical Medicine, with or without the term "Rehabilitation" being appended; therefore be it

Resolved, That the House of Delegates recommend to the Council on Physical Medicine and Rehabilitation that the name be changed to one more appropriate to the duties of that Council.

No. 6-A. Joint Resolutions from the Executive Committees of the Sections on Orthopedic Surgery, and Physical Medicine and Rehabilitation

WHEREAS, Certain resolutions have been introduced in the House of Delegates from the Section on Orthopedic Surgery relative to the deletion of the term "Rehabilitation" from the Board, Section, and Council on Physical Medicine and Rehabilitation; and

WHEREAS, At a meeting of a committee of the Board of Trustees with committees representing the Sections on Orthopedic Surgery, and Physical Medicine and Rehabilitation, and the Council on Medical Education and Hospitals, it was agreed that many basic principles are involved in the above-mentioned resolutions; therefore be it

Resolved, That action on the three resolutions from the Section on Orthopedic Surgery be deferred until the June, 1954, meeting of the House of Delegates of the American Medical Association; and be it further

Resolved, That the Board of Trustees of the American Medical Association be requested to appoint a committee composed of representatives of the various specialties most directly concerned with rehabilitation and, if deemed advisable, representatives of the Board of Trustees, to study the issues which have been raised, and to report to the House of Delegates in June, 1954, with recommendations relative to the following questions:

1. Should the Council on Physical Medicine and Rehabilitation be reorganized and renamed to indicate more clearly a primary function having to do with the investigation, standardization, and certification of medical equipment, apparatus, and materials?
2. Should another council be formed properly representative of the various branches of medicine which are concerned with rehabilitation, such council to be named, "The Council on Rehabilitation"?
3. Should the Section on Physical Medicine and Rehabilitation be renamed the "Section on Physical Medicine"?
4. Should the American Board of Physical Medicine and Rehabilitation be renamed?

Report of Reference Committee on Sections and Section Work

Dr. Jesse D. Hamer, Chairman, presented the following report, which was adopted:

Three resolutions, Nos. 4, 5, and 6, were introduced by Dr. Edward L. Compere, delegate of the Section on Orthopedic Surgery, and were before your committee for its consideration, as well as No. 6-A, a Joint Resolution from the Executive Committee of the Section on Orthopedic Surgery and the Section on Physical Medicine and Rehabilitation, which was introduced conjointly by Dr. Edward L. Compere, Section on Orthopedic Surgery, and Dr. Frank H. Krusen, Section on Physical Medicine and Rehabilitation.

Your reference committee, after due consideration of all the remarks made before it by representatives of these two sections, feels that the adoption by this House of Resolution No. 6-A would be the proper procedure in this instance. It would therefore recommend that Resolutions Nos. 4, 5, and 6 be tabled and that the content of Resolution No. 6-A be adopted.

No. 7. Resolutions on Improvement of Existing Voluntary Prepayment Medical Care Plans

Dr. W. W. Baum, for the Oregon State Medical Society, introduced the following resolutions, which were referred to the Reference Committee on Insurance and Medical Service:

WHEREAS, The American Medical Association and the physicians of the United States have strongly advocated voluntary health insurance; and

WHEREAS, This places on them a responsibility to make every effort to promote such prepaid medical coverage for all citizens whose circumstances make them eligible; and

WHEREAS, There are two large groups of citizens for whom improved coverage could be offered under present prepaid medical care plans, namely: (*a*) those individuals who suffer catastrophic or long-continued and highly expensive illness and whose financial resources are not adequate to meet the cost thereof and (*b*) those citizens who have retired and are living on small incomes and who are not eligible under presently existing public or private plans; and

WHEREAS, The Council on Medical Service of the American Medical Association is charged with the responsibility for investigations and recommendations in the field of prepaid medical care; therefore be it

Resolved, That this House of Delegates commend the Council on Medical Service for the excellent work it has done in this field in the past; and, as evidence of our continued confidence in its ability; be it further

Resolved, That this House of Delegates request the Council on Medical Service to proceed immediately with a special study of the two problems mentioned above and to present its findings and recommendations to the House of Delegates not later than the 1954 Clinical Meeting; and be it further

Resolved, That these findings and recommendations of the Council on Medical Service be published in some convenient form and made available not only to the medical profession but also to nonmedical groups or individuals working in the field of prepaid medical care.

Report of Reference Committee on Insurance and Medical Service

The report of the reference committee on Resolution No. 7 is contained in the next to the last paragraph of the committee's report on the report of the Council on Medical Service on page 1548 of this issue of THE JOURNAL.

No. 8. Resolutions on Dr. Elmer Lee Henderson

Dr. Clark Bailey, for the Kentucky delegation, introduced the following resolutions, which were adopted by a unanimous rising vote, without referral:

WHEREAS, In the passing of Dr. Elmer Lee Henderson of Louisville, Ky., on July 30, 1953, the nation lost one of its most honored citizens, and the people and medical profession of the world suffered an irreparable loss; and

WHEREAS, Dr. Henderson, one of medicine's most astute and effective statesmen, brought dignity, courage, and clear vision to his distinguished service as President of the Jefferson County Medical Society, the Kentucky State Medical Association, The Southern Medical Association, the American Medical Association, the World Medical Association, and the American Medical Education Foundation, as well as to his numerous other civic and professional activities; and

WHEREAS, Dr. Henderson, through his vigorous devotion to the cause of freedom in all phases of American life, provided long and continuous leadership, which immeasurably helped the people reaffirm their dedication to America's principles of liberty; now therefore be it

Resolved, That the House of Delegates of the American Medical Association gratefully acknowledge and affirm its deep appreciation for Dr. Henderson's unsparing work as physician, citizen, and medical leader, and his everlasting gifts to his fellow man; and be it further

Resolved, That the resolution of the House of Delegates of the American Medical Association be made a part of its permanent record and that a copy be sent to Mrs. Laura Henderson of Louisville, Ky., the bereaved widow, assuring her of our most sincere sympathy in the great loss that the entire medical profession all over the nation shares with her.

No. 9. Resolution on Unethical Practices

Dr. John F. Burton, Oklahoma, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Published statements of certain medical spokesmen concerning alleged unethical practices by members of the medical profession have tended to destroy the confidence of patients in their physicians, without solving the basic problems involved; and

WHEREAS, The American Medical Association has received requests calling for action to counteract this type of publicity; and

WHEREAS, This House of Delegates recognizes that the members of the American Medical Association look to the association to take steps leading to the elimination of publicity inimical to best physician-patient relationships, and to take steps to assure the highest quality of medical service; and

WHEREAS, This House of Delegates believes it necessary to determine the facts in reference to these published accusations; therefore be it

Resolved, That this House of Delegates direct the Speaker of the House of Delegates to appoint a special committee with broad representation throughout the profession whose function it shall be: (1) To study all aspects of the problems of public relations created by recent adverse publicity; (2) To study the problems of professional interrelationships such as are alleged in this publicity, particularly as they affect the quality and cost of medical care, utilizing whatever techniques are necessary to obtain factual information thereon; and (3) To report findings and submit recommendations for the solution of the above problems to the House of Delegates in June, 1954.

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, submitted the following report, which was adopted:

Res. No. 9 on Ethical Practices: This resolution has to do with published statements of certain medical spokesmen concerning alleged unethical practices by members of the medical profession which have tended to destroy the confidence of patients in their physicians without solving the basic problems involved. Your committee recognizes that the members of the American Medical Association look to the Association to take steps leading to the elimination of publicity inimical to the best physician-patient relationships and to take steps to assure the highest of medical service, and that it is also necessary to determine the facts in reference to these published accusations. In consultation with officers of the American Medical Association, your committee was informed that this study is already being undertaken. Your committee approves the intent of this resolution but believes that it would be difficult to implement as suggested in the "Resolved" portion. Therefore, your committee *recommends that this resolution be referred to the* Board of Trustees for further study and implementation, and directs the Board to appoint a special committee with broad representation throughout the profession to carry out the purposes of the resolution.

No. 10. Resolution on Social Security

Dr. Willard A. Wright, North Dakota, introduced the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, Legislation has been introduced into the Congress providing for the extension of compulsory coverage under Title II of the Social Security Act to self-employed persons, including physicians; and

Whereas, The House of Delegates has in the past registered its disapproval of the principle involved in this legislation; and

Whereas, Physicians desire the continued right to establish retirement benefits for themselves on a voluntary basis rather than being compelled to participate in a tax-supported government program which they do not want; and

Whereas, The Jenkins-Keogh bills (H.R. 10 and H.R. 11) now before the Congress provide for development of a voluntary pension program which is equitable, free from compulsion, and satisfies the retirement needs of physicians; therefore be it

Resolved, That this House of Delegates reaffirm its support and endorsement of the voluntary pension program provided in the Jenkins-Keogh bills and its strong opposition to the extension of compulsory coverage of physicians under Title II of the Social Security Act.

Report of Reference Committee on Legislation and Public Relations

The report of the reference committee on Resolution No. 10 is contained in its report on the report of the Committee on Legislation on page 1535 of this issue of The Journal.

No. 11. Resolution on Improvement of Rural Health

Dr. Willard A. Wright, North Dakota, presented the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

Whereas, Over the last few years the American Medical Association, through its Council on Rural Health and the constituent and component medical societies, has promoted a program designed to improve rural health; and

Whereas, This policy has been attended with such success that the medical profession has earned a place of high esteem among America's farm leaders and people; and

Whereas, Notwithstanding these successful efforts it is now recognized that there is need for further local support of the rural health program through cooperation among agricultural, medical, civic, and lay groups; therefore be it

Resolved, That this House of Delegates urge the constituent and component medical societies to organize rural health committees composed of personnel with an interest in rural health problems and an understanding of the needs for rural medical care, and to activate a rural health program in their respective communities.

Report of Reference Committee on Insurance and Medical Service

Dr. John M. Porter, Chairman, submitted the following report, which was adopted.

Your Reference Committee on Insurance and Medical Service had referred to it two major propositions, one concerning the work of the Council on Rural Health with one resolution referring to work of that council.

The Report of the Council on Rural Health speaks for itself and should be read by all of us who practice outside the metropolitan or industrial centers. If, because of isolation and sometimes apparently radical thinking, the farmer seems to require more than his share of attention or even subsidization, certainly we must agree that no better friend of medicine or more fundamentally necessary individual exists. In the opinion of your reference committee, the work of the Council on Rural Health, with its emphasis on education and its admirable record of cooperation with farm groups, should be continued and its efforts commended.

No. 12. Resolution on Abolition of Matching Plan for Internships

Dr. Charles L. Farrell, Rhode Island, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The "Matching Plan" instituted by the American Association for the apportionment of interns has frequently wc the detriment of smaller hospitals by depriving them of an adequ: cation of interns; and

Whereas, The smaller hospitals must still carry the bulk of pati and, to do so effectively, must have adequate house staffs; therefo

Resolved, By the House of Delegates of the American Medic ciation that the "matching" system of intern selection be abol

Report of Reference Committee on Medical Edu Hospitals

Dr. James Z. Appel, Chairman, submitted the report, which was adopted:

Your reference committee has received Resoluti introduced by Dr. Charles L. Farrell, Rhode Islan "Abolition of Matching Plan for Internships." Your committee enjoyed long debate by many membe Association and the comments of the representativ Student American Medical Association were very h no time during the debate was it pointed out how the plan *per se* is detrimental to the distribution of inte reference committee, therefore, recommends that th tion be rejected.

No. 13. Resolution on Listing of Accredited Ho

Dr. Charles L. Farrell, Rhode Island, presented the ing resolution, which was referred to the Reference Co on Medical Education and Hospitals:

Whereas, The Council on Medical Education and Hospitals h lished a list of Approved Internships revised to Sept. 1, 1953, tha the names and descriptions of hospitals which, though approved, ha subscribed to the Matching Plan, and then lists them supplement the general listing; and

Whereas, Such listing creates the impression that such hospita not of the same caliber or rating as the ones in the general listin

Whereas, This listing works to the disadvantage of hospitals s interns; therefore be it

Resolved, That the House of Delegates of the American Medical A ciation instruct the Council on Medical Education and Hospitals to re and republish immediately its listing to include all hospitals accredited intern training in one master list and to designate by column marking, asterisk or other device, those not subscribing to the Matching Plan.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, presented the following report, which was adopted:

Your reference committee received Resolution No. 13 introduced by Dr. Charles L. Farrell, Rhode Island, entitled "Listing of Accredited Hospitals by the Council on Medical Education and Hospitals."

Your reference committee recognizes that for economic reasons the Council has published a separate listing of hospitals that have subscribed to the Matching Plan and that segregation of nonmember hospitals might leave the inquiring intern and the general public to feel that such hospitals are discriminated against. Therefore, your reference committee wishes to present a substitute resolution as follows:

Resolved, That the House of Delegates of the American Medical Association instruct the Council on Medical Education and Hospitals at the appropriate time to publish a listing of all hospitals accredited for intern training in one master listing and to designate by bold face type or column marking those subscribing to the Matching Plan.

Your reference committee recommends the adoption of this substitute resolution.

No. 14. Resolution on More Equitable Distribution of Interns

Dr. Charles L. Farrell, Rhode Island, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, Many hospitals have offered internships out of proportion to bed capacity and clinical needs; and

Whereas, Many small hospitals accredited for internship are unable to secure sufficient interns and often secure none at all; and

Whereas, The only possible solution to this problem is a more equitable distribution of interns among accredited internships; therefore be it

Resolved, That the Council on Medical Education and Hospitals of the American Medical Association be instructed to take immediate steps to evaluate the actual needs of accredited hospitals for intern training and to develop a formula for equitable distribution that will insure interns for the smaller accredited hospitals.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, submitted the following report, which was adopted:

Your reference committee received Resolution No. 14 introduced by Dr. Charles L. Farrell, Rhode Island, entitled "More Equitable Distribution of Interns."

At the New York meeting of the House of Delegates in June, 1953, five resolutions on interns were considered by the Reference Committee on Medical Education and Hospitals. One of these resolutions was essentially the same as Resolution No. 14. Your House of Delegates approved a recommendation that a further study be made by a committee appointed by the Speaker of the House of Delegates, at least half of whom are doctors in private practice of medicine not connected with medical schools or affiliated hospitals. Furthermore, the Council on Medical Education and Hospitals has indicated in its report it is most willing and anxious to cooperate with this special committee. Your committee believes this special committee's charge will cover the content of Resolution No. 14 and therefore recommends that no action be taken at this time.

No. 15. Resolutions on Death of Dr. Frank Kells Boland

Dr. Eustace A. Allen, Georgia, introduced the following resolutions, which were adopted by a unanimous rising vote, without referral:

Whereas, Frank Kells Boland, a leading figure in the field of surgery for half a century, died Nov. 11. He was nationally known for his research in the history of anesthesia. It was through his efforts that Dr. Crawford W. Long was recognized as the discoverer of ether and anesthesia. He was the author of the book "The First Anesthetic," published in 1950; and

Whereas, He was interested in the history of medicine in Georgia and was also author of a book on the subject. He was a past president of the Atlanta Historical Society and was a member of numerous civic and fraternal organizations. He was a great leader in medical and surgical societies, having served as president of county, state, and medical alumni organizations and was also southeastern governor of the American College of Surgeons; and

Whereas, In the passing of this great medical leader, teacher of surgery, Georgia, the South, and the nation have lost one of its outstanding citizens. Dr. Boland, until the last, was always ready to serve his patients and all who called upon him for help. He never turned down a patient's call, and it is truly said that the spirit of service self-exemplified the man whose death will be mourned by all who knew him; therefore be it

Resolved, That the House of Delegates of the American Medical Association wishes to express its feeling of an irreplaceable loss in the death of Dr. Frank Kells Boland on Nov. 11, 1953; and be it further

Resolved, That a copy of these resolutions be forwarded to the family of our deceased friend.

No. 16. Resolution on Commission on *Intergovernmental Relations*

Dr. Vincent W. Archer, Virginia, introduced the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The President of the United States, under authority of the Congress, has appointed a Commission on Intergovernmental Relations, now known as the Manion Commission; and

Whereas, This commission has been charged with the responsibility of making inquiry into federal-state relations in reference to grants-in-aid and appropriations to states on a matching basis; and

Whereas, This inquiry will be concerned with the present status of such appropriations, the present and possible future needs and administrative set-ups as they now exist or should exist; therefore be it

Resolved, That the administrative body of each state and territorial medical society take immediate steps to contact the chairman of the commission in order to determine in what way the state society and appropriate state agencies can cooperate with the commission in aiding in the accomplishment of its purpose.

Report of Reference Committee on Miscellaneous Business

Dr. H. Gordon MacLean, Chairman, presented the following report, which was adopted:

Res. No. 16 on Commission on Intergovernmental Relations: Your committee approves the resolution that the administrative body of each state and territorial medical association take immediate steps to contact the chairman of the commission in order to determine in what way the state medical society and appropriate state agencies can cooperate with the Commission in aiding in the accomplishment of its purpose.

No. 17. Resolution on Veterans Care and Medical Training

Dr. John F. Burton, Oklahoma, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, There is a variance of opinion regarding the requirements of the bed ratio to student personnel for an approved school of medicine; and

Whereas, There are differences of opinion in regard to the question of rendering medical care and bedside teaching of medicine; therefore be it

Resolved, That the American Medical Association Board of Trustees, acting through the Council on Medical Education and Hospitals, initiate plans to solve these differences by: (1) establishing a bed ratio per student based upon the student personnel of the last two years of medicine, and (2) acting through the deans' committees, regulate medical attention rendered to veterans in Veterans Administration hospitals for teaching purposes by limiting to those cases of service-connected origin only.

Report of Reference Committee on Medical Education and Hospitals

Dr. James Z. Appel, Chairman, presented the following report, which was adopted:

Your reference committee received Resolution No. 17, introduced by John F. Burton, Oklahoma, entitled "Veterans Care and Medical Training."

It was pointed out to your reference committee that the teaching load ratio is a better method of measuring the number of patients per student than a bed ratio per student as advocated in this resolution. Your reference committee recommends that this portion of the resolution be rejected.

Your reference committee is in agreement with the American Medical Association policy that veterans care should be limited to those of service-connected origin with the exception of some specific cases. Your reference committee is also cognizant that it is the duty of physicians to render medical care whenever needed, and, so long as it is law and the administrative policy of the Veterans Administration to function along this line, it is necessary that the present program for medical students, interns, and residents in Veterans Administration hospitals be continued. Your reference committee therefore recommends that this portion of the resolution be rejected.

No. 17-A. Resolutions on the Late Dr. Edward D. Spalding

Dr. Robert L. Novy, Michigan, introduced the following resolutions, which were adopted by a unanimous rising vote, without referral:

Whereas, Dr. Edward D. Spalding, first alternate delegate representing the Michigan State Medical Society to the American Medical Association House of Delegates, was shot and killed as he departed from his office in Detroit to attend this Clinical Meeting of the American Medical Association; and

Whereas, At past sessions of this House, Dr. Spalding always was inspiring in his earnestness, in his energy, and in his brilliant mental capacity when attending to the duties assigned to him by the Michigan delegation to the American Medical Association House of Delegates; and

Whereas, Dr. Spalding, as an active practitioner of medicine, was a brilliant clinician as well as a militant leader in his espousal of private practice as opposed to compulsory schemes inimical to patients' welfare; therefore be it

Resolved, That the American Medical Association House of Delegates in session in St. Louis, Dec. 1-4, 1953, express its deep sense of loss in the tragic and abrupt passing of Dr. Edward D. Spalding and bespeaks its sincere sympathy to his bereaved survivors; and be it further

Resolved, That a copy of this resolution be prepared and be forwarded to Mrs. Spalding and to the Spalding family.

(Concluded in next issue.)

MEDICAL NEWS

CALIFORNIA

Research on Air Pollution.—A $78,084 grant has been made by the U. S. Public Health Service to the University of Southern California School of Medicine in Los Angeles to finance research on the effects of air pollution. Awarding of the research contract was announced on the 25th anniversary of the Southern California medical school, which was observed Sept. 24-25. Dr. Paul Kotin, Dr. Hurley Motley, John W. Mehl, Ph.D., and Hans Falk, Ph.D., will conduct the study.

Conference in Ophthalmology.—Stanford University School of Medicine, San Francisco, will present the annual postgraduate conference in ophthalmology, March 22-26, 1954. Registration will be open to 30 physicians who limit their practice to the treatment of diseases of the eye or of the eye, ear, nose, and throat. Instructors will be Drs. A. Edward Maumenee, Dohrmann K. Pischel, Jerome W. Bettman, Max Fine, Earle H. McBain, and Arthur J. Jampolsky. Information may be obtained from the Office of the Dean, Stanford University School of Medicine, 2398 Sacramento St., San Francisco 15.

Internists Meeting in Yosemite.—At the annual meeting in Yosemite National Park the California Society of Internal Medicine elected Dr. Walter Beckh, San Francisco, president, Dr. Paul I. Hoagland Jr., Pasadena, vice-president, and Dr. James H. Thompson, San Francisco, secretary-treasurer. The principal speaker, Homer W. Smith, Sc.D., professor of physiology, New York University College of Medicine, New York, discussed renal physiology, emphasizing "Salt and Water Balance." Other papers included "Acute Renal Failure—The Conservative Medical Management of Oliguria and Anuria" by Dr. James Hopper Jr. of the University of California Medical School, San Francisco, and "Acute Renal Failure—The Use of the Artificial Kidney" by Dr. Robert F. Maronde of the University of Southern California School of Medicine in Los Angeles. A medical economic forum was held to discuss the position of internists in the present day "surgical type" fee schedule.

COLORADO

State Medical Election.—At the annual meeting in Denver the Colorado State Medical Society chose the following officers: president, Dr. Claude D. Bonham, Boulder; president-elect, Dr. Samuel P. Newman, Denver; vice-president, Dr. Lawrence D. Buchanan, Wray; constitutional secretary (3 years), Dr. Irvin E. Hendryson, Denver; treasurer (3 years), Dr. Frank I. Nicks, Colorado Springs. The society will hold its next midwinter clinic at the Shirley-Savoy Hotel, Denver, Feb. 16-19, 1954, and the next annual session at the Broadmoor Hotel, Colorado Springs, Sept. 21-24.

Personal.—Dr. George W. Stiles, special research consultant, laboratory section, Colorado State Department of Public Health, Denver, has retired. Dr. Stiles came to the department in 1947 from the Bureau of Animal Industries.——Dr. Atha Thomas, chief of orthopedic surgery, University of Colorado School of Medicine, Denver, has been named chief of orthopedic service at National Jewish Hospital, which he has served as consultant orthopedic surgeon for many years.——Dr. Ruth Boring Howard, who has been acting chief of the hospitals standards and consultation section, Colorado State Department of Public Health, Denver, has been appointed chief of the maternal and child health section to replace Dr. Charles H. Dowding, who has accepted a position as deputy superintendent, maternal and child health, in the Milwaukee City Health Department.

CONNECTICUT

Flight Surgeons Needed.—Chief Flight Surgeon William B. Smith of the Connecticut Department of Aeronautics announces that he needs Air Force or Navy-trained flight surgeons for his examining staff in several parts of the state. Address all communications to Dr. William B. Smith, Chief Flight Surgeon, Connecticut Department of Aeronautics, Brainard Field, Hartford.

ILLINOIS

Psychiatric Lectures.—In its series on treatment in psychiatry, the North Shore Health Resort (225 Sheridan Road, Winnetka) offers the lecture "The Role of a Psychiatrist in a Hospital" by Dr. Howard P. Rome, Mayo Clinic, Rochester, Minn., who will speak Jan. 6, 1954, 8 p. m., at the health resort.

Edgar County Celebrates 50th Anniversary.—The Edgar County Medical Society marked its 50th anniversary Nov. 5 at a banquet given at the Elks' Club in Paris by the society and the women's auxiliary. The honored guest was Dr. Francis M. Link, Paris, the only living charter member. Dr. Paul E. Fleener, president of the society, presided.

Chicago

Personal.—Dr. Samuel M. Feinberg, professor of medicine and director of the Allergy Research Laboratory, Northwestern University Medical School, discussed "Allergy to Chemotherapy" at Coronado, Calif., Dec. 9, in the symposium "Acute Infectious Diseases" sponsored by the California Academy of General Practice and the Lederle Laboratories.

Course in Electrocardiographic Interpretation.—A course in electrocardiographic interpretation for graduate physicians will be given at Michael Reese Hospital by Dr. Louis N. Katz director of the cardiovascular department, Medical Research Institute, and associates, each Wednesday, 7-9 p. m. for 12 weeks, beginning Feb. 3, 1954. Information may be obtained on application to Mrs. Rivian H. Lewin, Cardiovascular Department, Michael Reese Hospital, Chicago 16.

Hospital News.—Dr. Karl A. Meyer, medical superintendent of Cook County institutions, announces the following appointments at Cook County Hospital: Dr. George C. Blaha medical director, Dr. Samuel Hyman, assistant medical superintendent, and Dr. Sinclair Howard Armstrong Jr., director of medical education. Dr. Armstrong, who is professor of medicine at the University of Illinois College of Medicine will also serve in an advisory capacity at the Hektoen Institute for Medical Research of the Cook County Hospital——A 27 million dollar slum redevelopment program involving 54 acres surrounding Michael Reese Hospital was recently approved by the Land Clearance Commission. The land will be cleared by the commission and sold to private interests for hospital expansion and rental housing purposes Dr. Morris H. Kreeger, executive director of the hospital, has announced (1) an immediate 6 million dollar program to build a 112-bed medical service building, 40-bed convalescent center central heating plant and new serum center and (2) an additional 4 million dollar program, to be completed in 10 years, which will include laboratory and research buildings, a center for studying the problems of the aging, and new nurses' and interns' residences.

IOWA

Public Medical Forums.—The Scott County Medical Society in cooperation with the Davenport Newspapers, Incorporated, held free physicians' public forums, Oct. 29, Nov. 3 and 19, and Dec. 3. Questions, submitted by the public and answered by a panel of physicians, concerned high and low blood pressure, weight, cancer, and rheumatic fever and rheumatic

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

heart disease. There was an average attendance of about 800. Dr. Harry B. Weinberg, Davenport, was general chairman of the project.

Personal.—Dr. Grace M. Sawyer, superintendent of the Woodward State Hospital and School, was honored at a reception given by the employees, at which Dr. Ben T. Whitaker, Boone, past president of the Iowa State Medical Society, gave greetings for that organization and Dr. Frank A. Wilke, Perry, spoke in behalf of the Dallas-Guthrie Medical Society. Dr. Sawyer came to the hospital and school in 1923, went into private practice in Woodward in 1935, and in 1938 returned to the hospital as assistant superintendent, being appointed acting superintendent in 1951 and superintendent last July.

MARYLAND

Dr. Friedenwald Honored.—Dr. Edgar B. Friedenwald, professor of clinical pediatrics, emeritus, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, received a testimonial at the annual pediatric symposium, which read in part: "We, his friends, colleagues and former students hereby honor him, in appreciation of his loyal and faithful service to all children; to Mercy Hospital Pediatrics; and to the medical school."

Dr. Peabody Relinquishes Chief Consultant's Duties.—Dr. J. Winthrop Peabody, chief visiting consultant, Glenn Dale Sanatorium, Washington, D. C., since 1939, recently terminated his services in that capacity in order to devote more time to private practice and to organizational activities. As a consultant, he will visit Glenn Dale once a week for chest conferences. Dr. Peabody was at one time superintendent of the sanatorium. A member of the faculty of Georgetown University School of Medicine, Washington, D. C., since 1921, he is presently professor of diseases of the respiratory system. He is a member of the Founders' Group of the American College of Chest Physicians, which he has served as president (1942-1944) and chairman of the Council on Postgraduate Medical Education since 1944. His son, Dr. Joseph Winthrop Peabody Jr., is a resident in thoracic surgery at the Veterans Administration Hospital in Oteen, N. C.

MINNESOTA

Dr. Ravitch Speaks on Intussusception.—The annual Phi Delta Epsilon lectureship, "Present Concepts in the Management of Intussusception," will be given by Dr. Marcus M. Ravitch, director, department of surgery, Mount Sinai Hospital, New York, on Jan. 7, 1954, 8 p. m., at Owre Amphitheater, University of Minnesota Medical School, Minneapolis.

Personal.—Dr. Randall G. Sprague, Rochester, was presented the first annual J. Howard Reber memorial medal by the Philadelphia Metabolic Association at a meeting of the association in Philadelphia. The medal was awarded to Dr. Sprague for the contribution to the work in the field of diabetes.——Dr. Henry E. Michelson, professor of dermatology, University of Minnesota Medical School, Minneapolis, recently delivered the William Allen Pusey memorial lecture of the Institute of Medicine of Chicago, "A Review and an Appraisal of the Present Knowledge of Lupus Erythematosus," before a joint meeting of the institute and the Chicago Dermatological Society in Chicago.

MISSOURI

University News.—The St. Louis University School of Medicine announces the following promotions: to the rank of associate professor, Drs. Wilbur K. Mueller and Don C. Weir, department of clinical radiology; and to assistant professor, Drs. James G. Janney Jr., James P. Murphy, J. Earl Smith, department of clinical medicine; Dr. Eugene G. Hamilton, clinical obstetrics and gynecology; Dr. Wilbert M. Gansloser, neurology and psychology; Drs. Ralph K. Earp, and Irwin B. Horwitz, orthopedic surgery; Dr. Edwin G. Eigel, clinical pediatrics; and Dr. Seymour Brown, clinical surgery.

NEBRASKA

Crippled Children's Clinics.—The clinics for crippled children are scheduled for the following dates: Jan. 9, 1954, Lexington, high school; Jan. 13, Norfolk, Norfolk State Hospital; Feb. 6, North Platte, high school; Feb. 20, Scottsbluff, St. Mary Hospital.

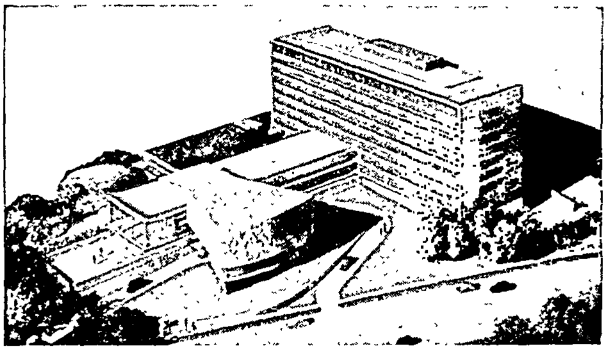
University News.—Creighton University recently honored six faculty members of the medical school in Omaha for 25 years' service. Plaques were presented to Drs. Michael J. Carey, Zeno N. Korth, Joseph W. McNamara, and James W. VaVerka, Leo P. Clements, Ph.D., Omaha, and to Dr. Isaac Sternhill, Council Bluffs, Iowa.

NEW YORK

Society News.—At the meeting of the Onondaga County Medical Society and Syracuse Academy of Medicine (304 McCarthy Building, Syracuse) Jan. 5, 1954, Dr. J. Englebert Dunphy of the Peter Bent Brigham Hospital, Boston, will discuss "The Role of the Surgeon in the Diagnosis, Treatment and Long Range Management of Cancer."

Lecture on Anesthetic Emergencies.—Drs. Merel H. Harmel, professor of anesthesiology, and Sylvan N. Surks, assistant professor of anesthesiology, State University of New York College of Medicine at New York City, Brooklyn, will discuss "Anesthetic Emergencies," Jan. 7, 1954, 8:30 p. m. at the Jewish Sanitarium and Hospital for Chronic Diseases, 86 E. 49th St., Brooklyn 3.

Albert Einstein College of Medicine.—Ground was broken on Oct. 25 for the 10 million dollar Albert Einstein College of Medicine of Yeshiva University at Morris Park Avenue and Eastchester Road, the Bronx. The 10-story building, shown in the illustration, will be the first unit of a 25 million dollar medical teaching center and is expected to be ready for occupancy in the fall of 1955, when the first class (100 freshmen) will be admitted. The faculty will consist of 300 full-time instructors and a larger number of part-time teachers. The college will adjoin the 1,400-bed Bronx Municipal Hospital Center, which the city of New York is constructing at an estimated cost of 40 million dollars and which will be affiliated with the college and serve as its clinical teaching center. Adjoining the 10-story teaching research building will be a 3-story administrative and library wing, from which will be projected a 750-seat fan-shaped auditorium. The teaching and research wing will consist of a basement, ground floor, seven major laboratory and teaching floors, an animal institute, and a mechanical equipment floor. Each floor above the second will contain 14 laboratories. There will be three two-story lecture halls, and three conference rooms. Speakers at the ground-breaking ceremony included Gov. Thomas E. Dewey, Ralph J. Bunche, Ph.D., director of the division of trusteeship of the United Nations, Mayor Vincent R. Impellitteri, Samuel Belkin, Ph.D., president of Yeshiva University, and Dr. Marcus D. Kogel, New York commissioner of hospitals. Nelson A. Rockefeller, undersecretary of the Department of Health, Education, and Welfare, addressed the dinner celebration following the ceremonies.



Albert Einstein College of Medicine of Yeshiva University.

New York City

Hospital News.—On Jan. 8, 1954, at 3 p. m., Dr. Jack Gross, assistant professor, department of anatomy, State University of New York College of Medicine at New York City, Brooklyn, will present "Some New Aspects of Thyroid Hormone Physiology" at the Montefiore Hospital for Chronic Diseases.

Meeting on Cancer.—The New York Cancer Society will discuss "Results to Date of Super-Radical Pelvic Surgery for Cancer," Jan. 5, 1954, 8:30 p. m., in the New York Academy of Medicine, Fifth Avenue at 103rd St. Dr. Perry B. Hudson will have as his topic "Cancer of the Bladder and Prostate" (discussion, Dr. Willet F. Whitmore Jr.), and Dr. Alexander Brunschwig will present "Cancer of the Uterus" (discussion, Dr. Howard C. Taylor Jr.). Physicians and medical students are invited.

Pfeiffer Research Foundation.—According to the will of the late Gustavus A. Pfeiffer, four-fifths of his residuary estate will go to the Gustavus and Louise Pfeiffer Research Foundation, which he and his wife established in 1942 for improving public health through the advancement of medicine and pharmacy. The former head of William R. Warner & Co., pharmaceutical manufacturers, and retired president of Richard Hudnut left an estate estimated at more than 10 million dollars.

Silkworth Memorial Service.—The Knickerbocker Hospital announces the opening of the Silkworth Memorial Service devoted to the study and treatment of deviant eating and drinking habits. Emphasis will be given to obesity and alcoholism and the inter-relation of the physiological and medical aspects and the patient's emotional and social problems. A diagnostic evaluation, carried out by the service on all referred patients, will cover the medical, psychological, and social areas. Dr. Giorgio Lolli, director of the new service, will continue to be medical director of the Yale Plan Clinic, Yale University, New Haven, Conn., a position he has held for many years. To accept the direction of the Silkworth Memorial Service, he has resigned from the position of medical director of the Connecticut Commission on Alcoholism. He will, however, continue his association with the commission as a consultant.

OKLAHOMA

Surgery Course Postponed.—The University of Oklahoma School of Medicine, Oklahoma City, announces that the postgraduate study course in surgery originally scheduled for Dec. 9-11 has been postponed to Jan. 6-8, 1954. In addition to the staff of the School of Medicine, the faculty will include three visiting guest speakers: Dr. John T. Reynolds, associate professor of surgery, University of Illinois College of Medicine, Chicago, who will discuss problems of the gastrointestinal tract; Dr. Michael E. DeBakey, professor of surgery, Baylor University College of Medicine, Houston, Texas, who will speak on surgical management of diseases of the aorta; and Dr. John W. Duckett, professor of clinical surgery, Southwestern Medical School, Dallas, Texas, who will present some problems of pediatric surgery.

TENNESSEE

Fifty Year Club.—At a special dinner meeting of the Memphis-Shelby County Medical Society, Oct. 6, at the Memphis Country Club, Drs. George R. Livermore, William H. Lovejoy, and Wallace P. Moore of Memphis and Dr. Logan C. McVay of Marion, Ark., were awarded certificates of recognition for their long service by the society and were presented with 50 year gold pins from the Tennessee State Medical Association. Dr. McVay recently received a 50 year pin from the Arkansas Medical Society.

TEXAS

Narcotic Violation.—Dr. Thomas Calvin Brackeen, 770½ Neches, Beaumont, pleaded guilty on Nov. 4 in the U. S. District Court at Beaumont to a violation of the federal narcotic law. On Nov. 5, he was sentenced to serve two years each on five counts, to run concurrently, and was fined $300 on each of the five counts. The sentence was suspended, and he was placed on probation for three years.

University News.—Dr. William F. Mengert, professor of obstetrics and gynecology, Southwestern Medical School of the University of Texas, Dallas, has been appointed chairman of the obstetrics and gynecology test committee of the National Board of Medical Examiners.——At the recent meeting of the Association of American Medical Colleges in Atlantic City, Dr. George N. Aagaard, dean of Southwestern Medical School of the University of Texas, was elected a member of the executive council for a three year term.

WEST VIRGINIA

Civil Defense Meeting.—At a combined staff meeting of the state and local health department personnel in Charleston, Dec. 14-15, Dr. Newman H. Dyer, state director of health, presided over a civil defense meeting of the medical and health services division of the West Virginia civil defense program. Dr. Henry C. Huntley, formerly of Charleston but now medical officer of the Regional Office, Federal Civil Defense Administration, West Chester, Pa., discussed the "Status of the Civil Defense Program at Regional Level," and Lt. Col. Edgar M. Sites, deputy C. D. director for West Virginia, presented "The General State Program." Dr. Leon A. Dickerson, director, Kanawha-Charleston Health Department, spoke on the role of the health officer, medical profession, advisory committee, voluntary agency, and the hospital in civil defense. The program also featured addresses by Dr. James S. Klumpp, Huntington, president, West Virginia State Medical Association; Dr. Russell Kessel, Charleston, president-elect; Mr. T. A. Baxter, state representative of the American Red Cross; and Mr. William R. Huff, executive secretary of the West Virginia Hospital Association.

ALASKA

Personal.—Dr. Arthur N. Wilson of Ketchikan has been appointed a member of the Alaska Board of Health.——Dr. Hazel I. Blair, Juneau, senior field physician for the health department, has been granted a year's leave of absence.——Dr. John T. Gentry, who was assigned by the U. S. Public Health Service as the first full-time health officer for the Greater Anchorage Health District in September, 1952, has resigned to fulfil a service obligation at the New York State Department of Health that was postponed because of his work with the U. S. Public Health Service.

Mental Health Association.—The Juneau Mental Health Association has elected its first board of directors, which includes Drs. Norman J. Diamond and Joseph O. Rude, Juneau. The organization, which consists of 41 members, was formed "to promote good mental health, to prevent mental and emotional illness, and to speed the day when any person who becomes mentally and emotionally ill will have the best possible chance to get well." Working committees include legislative, education, public relations, and mental health facilities. One of the first activities of the legislative committee is its work to encourage passage of HR 1217, a bill presently in congress, which seeks to improve treatment and care of Alaska's mentally ill. The association may be contacted through Mrs. Tickell, Box 1177, Juneau.

LATIN AMERICA

School for Study of Ophthalmology.—The Liga contra la Ceguera of Cuba will open a new school of specialization in ophthalmology in Havana, offering a two year course with theoretical and practical training and a one year postgraduate course. Dr. Thomas R. Yanes is head of the school. The first course will start in July, 1954, consisting of four semesters, up to a total of 800 hours. The tuition is $500, payable in two semesters. The first matriculation is restricted to 20 candidates, including Americans and Latin Americans, in practice for less than five years. Information may be obtained from the secretary of the school, M. Farinas Pelletier, Liga contra la Ceguera, Apartado de Correos 4053, Havana, Cuba.

GENERAL

Reports Wanted on Disaster Research.—The National Academy of Sciences-National Research Council has set up a committee on disaster studies under the council's division of anthropology and psychology. Because of the interest in disaster research, the many disciplines involved, and the great need for exchange of information, the committee has established a clearinghouse for disaster studies, is anxious to receive reprints and reports, especially unpublished reports, on disaster studies, and would appreciate communication with the investigators of any "in progress" studies. Correspondence may be addressed to the chairman, Mr. C. M. Louttit, National Academy of Sciences, 2101 Constitution Ave., Washington 25, D. C.

Cerebral Palsy Grants.—During the 12 months ending Sept. 30, United Cerebral Palsy allotted research and training grants totaling $392,874. Research grants, $254,940, reflected a 69% increase over the previous year. The new grants, which have widened the scope of research being sponsored by United Cerebral Palsy to include such investigations as a study of breathing movements in cerebral palsy and a study of factors promoting regeneration of nerve fibers in the central nervous system, are in addition to long-range studies begun in previous years. This year there were seven workshops, at which 116 educational and professional specialists and 52 counselors of the handicapped and social workers learned about special education and vocational planning for the palsied.

Society News.—At the annual meeting, Oct. 30-31, in Fort Worth, Texas, the **American Academy for Cerebral Palsy** chose Dr. Meyer A. Perlstein, Chicago, president and Dr. Lenox D. Baker, Durham, N. C., president-elect.——Officers of the **New England Society of Anesthesiologists** for the coming year are Dr. Stevens J. Martin, Hartford, Conn., president, Dr. Elihu Saklad, Providence, R. I., vice-president, and Dr. Francis J. Audin, Boston, secretary-treasurer.——At the annual meeting of the **Neurosurgical Society of America** at Colorado Springs, Colo., the following officers were elected: Dr. C. Douglas Hawkes, Memphis, president; Drs. Carl J. Graf, Buffalo, and Charles L. Neill, Jackson, Miss., vice-presidents; Dr. I. Joshua Speigel, Chicago, treasurer; and Dr. Lester A. Mount, New York, secretary.

Mississippi Valley Essay Contest.—The Mississippi Valley Medical Society offers a cash prize of $100, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest and of practical value to the general practitioners. Contestants must be members of the American Medical Association who are residents and citizens of the United States. The winner of the 1954 contest will be invited to present his contribution before the 19th annual meeting of the Mississippi Valley Medical Society, Chicago, Sept. 23-24, 1954. Contributions must be typewritten in English in manuscript form, submitted in five copies, not to exceed 5,000 words, and received not later than May 1. Details may be secured from Dr. Harold Swanberg, secretary, Mississippi Valley Medical Society, 209-224 W.C.U. Building, Quincy, Ill.

Meeting for Hospital Consultants.—At the annual convention of the American Association for the Advancement of Science the association will hold a joint session with the American Association of Hospital Consultants, Dec. 30, 9:30 a. m., at the Hotel Statler, Boston. Dr. E. Michael Bluestone, New York, president, American Association of Hospital Consultants, will preside over the following program on the research function of the hospital:

Varieties of Laboratory Service in Hospitals, Jack Masur, Washington, D. C.

A Hospital Research Program—Experiences at the Massachusetts General Hospital, Dean A. Clark, Boston.

Developments in Physical and Chemical Research (Including Atomic Research) Which Have a Relationship to Hospital Laboratories, G. Harvey Agnew, Toronto, Canada.

The discussion will be opened by Dr. Cecil G. Sheps, Boston.

Meeting on Premedical Education.—At the meeting of the American Association for the Advancement of Science, Boston, Alpha Epsilon Delta, national premedical honor society, will sponsor a luncheon at the Hotel Statler, 12:15 p. m., Dec. 29. "The Need for More Well Qualified Applicants for the Medical Schools" will be discussed by Dr. James M. Faulkner, dean, Boston University School of Medicine, and "Suggestions on a Second National Conference on Premedical Education" will be presented by the fraternity's national secretary, Maurice L. Moore. Informal round-table discussion will follow. Members of Alpha Epsilon Delta and others interested in premedical education are invited to attend the luncheon and program. Reservations for luncheon ($2.50, including gratuities) should be made through the National Secretary, Alpha Epsilon Delta, 7 Brookside Circle, Bronxville 8, N. Y.

Committee to Certify Mental Hospital Administrators.—The American Psychiatric Association has set up a committee to certify physicians as "qualified mental hospital administrators," in order to help ensure that the chief executives of mental hospitals shall be physicians not only adequately trained in psychiatry but also skilled in business and personnel management, community relations, budget control, procurement, and other essential administrative techniques. The committee, which will conduct examinations periodically, comprises: Drs. Francis J. Braceland, Hartford, Conn. (chairman); William B. Terhune, New Canaan, Conn.; George W. Jackson, Topeka, Kan.; Walter H. Baer, Peoria, Ill.; Granville L. Jones, Williamsburg, Va.; Frank F. Tallman, Los Angeles; Arthur M. Gee, Essondale, British Columbia, Canada; Harold W. Sterling, North Little Rock, Ark.; Jack R. Ewalt, Boston; and G. Wilse Robinson, Kansas City, Mo. Information may be obtained from the secretary, Dr. Crawford N. Baganz, Manager, Veterans Administration Hospital, Lyons, N. J.

FOREIGN

Society News.—The Association of Pediatricians of India, of which G. Coelho is chairman and R. V. Sanzgiri, secretary, has its headquarters at Back Bay View, New Queen's Road, Bombay 4.

International Orthopedic Surgery Meeting.—The sixth congress of the International Society of Orthopaedic Surgery and Traumatology will be held in Bern, Switzerland, Aug. 30 to Sept. 3, 1954. The tentative program includes treatment of scoliosis, physiology of sport, physiology of movement, chemical aspects of orthopedic surgery, bone and joint tuberculosis, bone and joint pathology, and surgery of the hand. Visits to nearby hospitals, research centers, and other institutions have been scheduled, as well as excursions at the close of the congress. Correspondence should be addressed to the secretary-general of the society, Dr. Jean Delchef, 34, rue Montoyer, Brussells, Belgium. Application should be made before May 31.

Prize for Study on Alcoholism.—The Society for the Study of Addiction has opened the competition for the Hubert Norman prize of 100 guineas (about $296) to stimulate research on the cause and prevention of addiction. The competition is open to both medical and nonmedical workers throughout the world, only officers of the society being ineligible. The subject of the first Hubert Norman prize will be: "Study or Investigation of Substances, Other Than Antabuse or Its Derivatives, Causing Distaste, Disinclination, or Dislike for Alcohol." Three copies of the manuscript, typewritten in English, should reach the editor of the *British Journal of Addiction*, 34 Addison Road, London, W.14, not later than Dec. 31, 1954. The award will be made in January, 1955. The selected contribution may be published in the journal and the winner invited to present it at a meeting of the society. Inquiries concerning the competition should be addressed to the editor of the journal.

CORRECTIONS

Dr. Sabin Not First Woman Graduate of Johns Hopkins.—The statement that Dr. Florence R. Sabin was the first woman to be admitted to and to graduate from Johns Hopkins University School of Medicine, which appeared in THE JOURNAL, Nov. 14, page 1030, was erroneous. Dr. Sabin was among the 13 women who received the M.D. degree in 1900 from Johns Hopkins. The first graduating class (1897) contained one woman, Mary Secord Packard.

New York City

Hospital News.—On Jan. 8, 1954, at 3 p. m., Dr. Jack Gross, assistant professor, department of anatomy, State University of New York College of Medicine at New York City, Brooklyn, will present "Some New Aspects of Thyroid Hormone Physiology" at the Montefiore Hospital for Chronic Diseases.

Meeting on Cancer.—The New York Cancer Society will discuss "Results to Date of Super-Radical Pelvic Surgery for Cancer," Jan. 5, 1954, 8:30 p. m., in the New York Academy of Medicine, Fifth Avenue at 103rd St. Dr. Perry B. Hudson will have as his topic "Cancer of the Bladder and Prostate" (discussion, Dr. Willet F. Whitmore Jr.), and Dr. Alexander Brunschwig will present "Cancer of the Uterus" (discussion, Dr. Howard C. Taylor Jr.). Physicians and medical students are invited.

Pfeiffer Research Foundation.—According to the will of the late Gustavus A. Pfeiffer, four-fifths of his residuary estate will go to the Gustavus and Louise Pfeiffer Research Foundation, which he and his wife established in 1942 for improving public health through the advancement of medicine and pharmacy. The former head of William R. Warner & Co., pharmaceutical manufacturers, and retired president of Richard Hudnut left an estate estimated at more than 10 million dollars.

Silkworth Memorial Service.—The Knickerbocker Hospital announces the opening of the Silkworth Memorial Service devoted to the study and treatment of deviant eating and drinking habits. Emphasis will be given to obesity and alcoholism and the inter-relation of the physiological and medical aspects and the patient's emotional and social problems. A diagnostic evaluation, carried out by the service on all referred patients, will cover the medical, psychological, and social areas. Dr. Giorgio Lolli, director of the new service, will continue to be medical director of the Yale Plan Clinic, Yale University, New Haven, Conn., a position he has held for many years. To accept the direction of the Silkworth Memorial Service, he has resigned from the position of medical director of the Connecticut Commission on Alcoholism. He will, however, continue his association with the commission as a consultant.

Douglas Hawkes, Memphis, president; Drs. Carl J. Graf, Buffalo, and Charles L. Neill, Jackson, Miss., vice-presidents; Dr. I. Joshua Speigel, Chicago, treasurer; and Dr. Lester A. Mount, New York, secretary.

Mississippi Valley Essay Contest.—The Mississippi Valley Medical Society offers a cash prize of $100, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest and of practical value to the general practitioners. Contestants must be members of the American Medical Association who are residents and citizens of the United States. The winner of the 1954 contest will be invited to present his contribution before the 19th annual meeting of the Mississippi Valley Medical Society, Chicago, Sept. 23-24, 1954. Contributions must be typewritten in English in manuscript form, submitted in five copies, not to exceed 5,000 words, and received not later than May 1. Details may be secured from Dr. Harold Swanberg, secretary, Mississippi Valley Medical Society, 209-224 W.C.U. Building, Quincy, Ill.

Meeting for Hospital Consultants.—At the annual convention of the American Association for the Advancement of Science the association will hold a joint session with the American Association of Hospital Consultants, Dec. 30, 9:30 a. m., at the Hotel Statler, Boston. Dr. E. Michael Bluestone, New York, president, American Association of Hospital Consultants, will preside over the following program on the research function of the hospital:

Varieties of Laboratory Service in Hospitals, Jack Masur, Washington, D. C.

A Hospital Research Program—Experiences at the Massachusetts General Hospital, Dean A. Clark, Boston.

Developments in Physical and Chemical Research (Including Atomic Research) Which Have a Relationship to Hospital Laboratories, G. Harvey Agnew, Toronto, Canada.

The discussion will be opened by Dr. Cecil G. Sheps, Boston.

Meeting on Premedical Education.—At the meeting of the American Association for the Advancement of Science, Boston, Alpha Epsilon Delta, national premedical honor society, will sponsor a luncheon at the Hotel Statler, 12:15 p. m., Dec. 29. "The Need for More Well Qualified Applicants for the Medical Schools" will be discussed by Dr. James M. Faulkner, dean, Boston University School of Medicine, and "Suggestions on a Second National Conference on Premedical Education" will be presented by the fraternity's national secretary, Maurice L. Moore. Informal round-table discussion will follow. Members of Alpha Epsilon Delta and others interested in premedical education are invited to attend the luncheon and program. Reservations for luncheon ($2.50, including gratuities) should be made through the National Secretary, Alpha Epsilon Delta, 7 Brookside Circle, Bronxville 8, N. Y.

Committee to Certify Mental Hospital Administrators.—The American Psychiatric Association has set up a committee to certify physicians as "qualified mental hospital administrators," in order to help ensure that the chief executives of mental hospitals shall be physicians not only adequately trained in psychiatry but also skilled in business and personnel management, community relations, budget control, procurement, and other essential administrative techniques. The committee, which will conduct examinations periodically, comprises: Drs. Francis J. Braceland, Hartford, Conn. (chairman); William B. Terhune, New Canaan, Conn.; George W. Jackson, Topeka, Kan.; Walter H. Baer, Peoria, Ill.; Granville L. Jones, Williamsburg, Va.; Frank F. Tallman, Los Angeles; Arthur M. Gee, Essondale, British Columbia, Canada; Harold W. Sterling, North Little Rock, Ark.; Jack R. Ewalt, Boston; and G. Wilse Robinson, Kansas City, Mo. Information may be obtained from the secretary, Dr. Crawford N. Baganz, Manager, Veterans Administration Hospital, Lyons, N. J.

FOREIGN

Society News.—The Association of Pediatricians of India, of which G. Coelho is chairman and R. V. Sanzgiri, secretary, has its headquarters at Back Bay View, New Queen's Road, Bombay 4.

International Orthopedic Surgery Meeting.—The sixth congress of the International Society of Orthopaedic Surgery and Traumatology will be held in Bern, Switzerland, Aug. 30 to Sept. 3, 1954. The tentative program includes treatment of scoliosis, physiology of sport, physiology of movement, chemical aspects of orthopedic surgery, bone and joint tuberculosis, bone and joint pathology, and surgery of the hand. Visits to nearby hospitals, research centers, and other institutions have been scheduled, as well as excursions at the close of the congress. Correspondence should be addressed to the secretary-general of the society, Dr. Jean Delchef, 34, rue Montoyer, Brussells, Belgium. Application should be made before May 31.

Prize for Study on Alcoholism.—The Society for the Study of Addiction has opened the competition for the Hubert Norman prize of 100 guineas (about $296) to stimulate research on the cause and prevention of addiction. The competition is open to both medical and nonmedical workers throughout the world, only officers of the society being ineligible. The subject of the first Hubert Norman prize will be: "Study or Investigation of Substances, Other Than Antabuse or Its Derivatives, Causing Distaste, Disinclination, or Dislike for Alcohol." Three copies of the manuscript, typewritten in English, should reach the editor of the *British Journal of Addiction*, 34 Addison Road, London, W.14, not later than Dec. 31, 1954. The award will be made in January, 1955. The selected contribution may be published in the journal and the winner invited to present it at a meeting of the society. Inquiries concerning the competition should be addressed to the editor of the journal.

CORRECTIONS

Dr. Sabin Not First Woman Graduate of Johns Hopkins.—The statement that Dr. Florence R. Sabin was the first woman to be admitted to and to graduate from Johns Hopkins University School of Medicine, which appeared in THE JOURNAL, Nov. 14, page 1030, was erroneous. Dr. Sabin was among the 13 women who received the M.D. degree in 1900 from Johns Hopkins. The first graduating class (1897) contained one woman, Mary Secord Packard.

Hans L. Popper.—The senior author of the Clinical Note in The Journal, Nov. 21, 1953, page 1095, entitled "Ligation of Hepatic Artery for Portal Hypertension" was Hans Leopold Popper, M.D. A second physician in Chicago with a similar name (Hans Popper, M.D.) is on the staff at the Hektoen Institute of the Cook County Hospital.

The Bolen Test for Cancer.—In queries and Minor Notes in The Journal, June 21, 1952, page 797, the reference to the two journals mentioned in the last three lines of the first paragraph in the answer were erroneous and should have referred to the *American Journal of Surgery*, November, 1950, and to the *American Journal of Digestive Diseases*, February, 1950.

EXAMINATIONS AND LICENSURE

National Board of Medical Examiners: *Parts I and II.* Held in approved medical schools where there are five or more candidates. Dates: Feb 9-10; April 20-21 (Part II only); June 22-23; Sept. 7-8 (Part I only). Candidates may file examinations at any time but the National Board must receive them at least six weeks before the date of the examination they wish to take. New candidates should apply by formal registration; registered candidates should notify the board by letter. Sec., Dr. John P. Hubbard, 133 S. 36th St., Philadelphia 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Hawaii: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Jan. 26-28. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 16-18. Exec. Sec., Miss Ruth V. Kirk, 538 K of P Bldg., Indianapolis.

Massachusetts: *Examination.* Boston, Jan. 12-15. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Michigan:* *Examination.* Detroit and Ann Arbor, June 1954. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Montana: *Reciprocity.* Helena, April 5. *Examination.* Helena, April 6-7. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity.* Reno, Jan. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, March 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* *Examination and Reciprocity.* Santa Fe, April 12-13. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, Syracuse and New York City, Feb. 16-19. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Winston-Salem, Jan. 18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Oklahoma:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, Jan. 4-5. *Reciprocity.* Portland, Jan. 14-16. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Jan. 7-8. Admin. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity.* Columbia, Feb. 1. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Vermont: *Examination.* Burlington, Feb. 1954. Sec., Dr. F. J. Lawliss, Richford.

Washington:* *Examination.* Seattle, Jan. 10-13. *Reciprocity.* Seattle, Jan. 10. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: *Examination and Reciprocity.* Charleston, Jan. 11-13. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: *Oral Examination and Reciprocity.* Cheyenne, Feb. 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Connecticut: *Examination.* New Haven, Feb. 13. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

Iowa: *Examination.* Des Moines, Jan. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, Feb. 12-13. Sec., Mrs. Anne Baker, 410 W. Allegan St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Jan. 5-6. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Minneapolis 14.

Nevada: *Examination.* Reno, Jan. 5. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

New Mexico: *Examination.* Santa Fe, Jan. 17. Sec., Miss Marguerite K. Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, March 6, June 5, Sept. 11 and Dec. 4. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Tennessee: *Examination.* Memphis, Dec. 30-31. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* April 1954. Location determined by number of applicants from different sections of the state. Sec., Brother Raphael Wilson, C.S.C., 407 Perry-Brooke Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 6-7. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

Wisconsin: *Examination.* Madison, April 3 and June 5. Final date for filing application is March 26 and May 28. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

*Basic Science Certificate required.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

Annual Congress on Medical Education and Licensure, Palmer House, Chicago, Feb. 7-9. Dr. Edward L. Turner, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, Shamrock Hotel, Houston, Texas, Feb. 1-3. Dr. Alan G. Cazort, 1425 West 7th St., Little Rock, Ark., Secretary.

American Academy of Occupational Medicine, John Marshall Hotel, Richmond, Va., Feb. 11-12. Dr. Leonard J. Goldwater, 600 W. 168th St., New York 32, Secretary.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

DEATHS

Boland, Frank Kells ⊕ Atlanta, Ga.; born in Indianapolis May 3, 1875; Atlanta College of Physicians and Surgeons, 1900; intern and later resident in surgery at St. Joseph's Hospital in Baltimore until 1903 when he returned to Atlanta to practice; joined the faculty of his alma mater, now Emory University School of Medicine, in 1903 as demonstrator of anatomy; professor of operative and clinical surgery when his alma mater was known as Atlanta School of Medicine, serving from 1905 to 1913 and professor of clinical surgery from 1913 to 1915; formerly professor of surgery and clinical surgery at Emory University School of Medicine, where from 1937 to 1946 he was a member of the board of trustees and at the time of his death was Joseph Brown Whitehead professor of surgery and chairman of the department; professor of anatomy at Emory University School of Dentistry from 1907 to 1919 and professor of physiology from 1919 to 1949; formerly vice-chairman, Section on Surgery, General and Abdominal, American Medical Association; past president of the Southern Medical Association, of which he served as chairman and secretary of the surgical section, vice-president, and chairman of the council; past president and vice-president of the Southern Surgical Association; past president and secretary-treasurer of the Chattahoochee Valley Medical Association; past president of the Atlanta Historical Society, Medical Association of Georgia, Fulton County Medical Society, Southeastern Surgical Congress, University of Georgia Alumni Society, which in 1940 awarded him a citation for distinguished service, and the Emory University Alumni Association; member of the American Surgical Association, American Association for the Surgery of Trauma, American Association for Thoracic Surgery, Société Internationale de Chirurgie, Chi Phi, Phi Beta Kappa, Phi Beta Kappa Associates, Phi Chi, and Omicron Delta Kappa; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; during World War I was chief of the surgical service at Base Hospital 43, in Blois, France, where the Emory unit was stationed, and later was appointed colonel, Medical Officers Reserve Corps; chairman of the Atlanta chapter, American Red Cross, from 1938 to 1942; president of the Atlanta chapter, English Speaking Union, since 1942; president of the Crawford W. Long Memorial Association; consulting surgeon, Georgia Baptist Hospital; surgeon, Crawford W. Long Memorial, Grady Memorial, and Piedmont hospitals, St. Joseph's Infirmary, and Emory University Hospital; in 1926 was given the degree of doctor of science at the University of Georgia; on the editorial board of the *American Surgeon*; author of "The First Anesthetic: The Story of Crawford Long"; died Nov. 11, aged 78, of nephritis and uremia.

Thompson, Alvin ⊕ Flint, Mich.; born in Racine, Wis., Dec. 12, 1880; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; specialist certified by the American Board of Urology; member of the American Urological Association; past president of the Genesee County Medical Society and the Flint Academy of Surgery; at one time taught at Rush Medical College and Northwestern Dental School in Chicago, and was secretary-treasurer of the Chicago Urological Society; fellow of the American College of Surgeons; on the staffs of Hurley, St. Joseph, and McLaren hospitals; died Oct. 22, aged 72, of arteriosclerotic heart disease.

Menk, Paul Ernest ⊕ Phoenix, Ariz.; Columbia University College of Physicians and Surgeons, New York, 1900; also a graduate in pharmacy; member of the Medical Society of New Jersey and the American Urological Association; specialist certified by the American Board of Urology; formerly practiced in Newark, N. J., where he was affiliated with Clara Maass Memorial Hospital, Babies' Hospital-Coit Memorial, Hospital of St. Barnabas and for Women and Children, Newark City Hospital, St. James Hospital, Irvington (N. J.) General Hospital, and Overlook Hospital in Summit; died Oct. 24, aged 76, of arteriosclerotic heart disease.

Sanford, Conley Hall ⊕ Memphis, Tenn.; born in Dyer, Tenn., Sept. 12, 1893; University of Tennessee College of Medicine, Memphis, 1918; interned at the Philadelphia General Hospital; served during World War I; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; since 1939 professor of medicine and chief of the division of medicine at his alma mater, from which he recently retired; recently retired as chief of staff at John Gaston Hospital; on the staff of the Baptist Memorial Hospital; died in Whitehaven Nov. 16, aged 60.

Abramson, Arthur Joseph ⊕ San Francisco; University of California Medical School, San Francisco, 1937; served during World War II; died Oct. 27, aged 46, of myocardial infarction and arteriosclerosis.

Anderson, Charles Rhodes ⊕ Winchester, Va.; University of Maryland School of Medicine, Baltimore, 1908; for many years member of the city council and mayor of Winchester; served during World War I; secretary of the Frederick County Board of Health; on the staff of Winchester Memorial Hospital; past president of the Chamber of Commerce; a director of the Commercial and Savings Bank; died Oct. 24, aged 75.

Barnes, Tiffany, Asheboro, N. C.; Medical College of Virginia, Richmond, 1925; member of the American Academy of General Practice; on the staff of Griffin Clinic-Hospital and Randolph Hospital; died Oct. 29, aged 55, of hemorrhage from esophageal varices.

Buckner, Frank Ingram ⊕ Campbellsville, Ky.; University of Louisville Medical Department, 1913; county health officer; served as county coroner; formerly member of the city council and the city board of education; died in the Rosary Hospital Oct. 13, aged 65.

Burnett, Harry Webster ⊕ Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1915; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; on the consulting staff, Miami Valley Hospital, where he died Nov. 6, aged 61, of coronary disease.

Green, Edgar Vernon, Youngsville, N. C.; Emory University School of Medicine, Atlanta, 1937; affiliated with Franklin Memorial Hospital in Louisburg; died Oct. 14, aged 40, of injuries received in an automobile accident.

Green, Thaddeus Hall, St. Petersburg, Fla.; Atlanta Medical College, 1914; died Sept. 16, aged 63, of acute myocardial infarction.

Hanlon, Clement Richard ⊕ Bethlehem, Pa.; Jefferson Medical College of Philadelphia, 1936; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; affiliated with Robert Packer Memorial Hospital in Sayre, Easton (Pa.) Hospital and St. Luke's Hospital; died Oct. 18, aged 43, of coronary occlusion.

Hardman, Charles Terrell ⊕ Tallulah Falls, Ga.; Emory University School of Medicine, 1917; served as chairman of the board of trustees of the Tallulah Falls School and as physician for the Georgia Power Company; died in Emory University (Ga.) Hospital Oct. 4, aged 65, of rupture of aortic aneurysm.

Hartzell, Homer John ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1902; held teaching appointments in the departments of chemistry and pharmacology at Western Reserve University School of Medicine, where, from 1919 to 1935, he taught ophthalmology; for many years consultant in eye diseases to the city public schools; at various periods on the staffs of old Lakeside Hospital and St. John's Hospital; died Nov. 1, aged 80, of carcinoma of the pancreas.

⊕ Indicates Member of the American Medical Association.

Hendrickson, Harold Wesley ⊕ Cedarville, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1940; served during World War II; affiliated with Bridgeton (N. J.) Hospital, where he died Oct. 25, aged 40, of coronary occlusion.

Hertel, Paul, Chicago; Bennett Medical College, Chicago, 1915; served during World War I; died in the Alexian Brothers' Hospital Nov. 18, aged 75, of peritonitis, pararectal abscess, and carcinoma of the rectum.

Hogan, Austin ⊕ Johnstown, N. Y.; University and Bellevue Hospital Medical College, New York, 1902; died Aug. 26, aged 76, of cerebral hemorrhage and hypertensive cardiovascular disease.

Howell, John Valentine ⊕ Marion, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; died in the Perry County Hospital Aug. 20, aged 56, of acute coronary thrombosis.

Jackson, William Henry, Louisville, Ky.; Meharry Medical College, Nashville, Tenn., 1911; died Oct. 7, aged 68.

Jones, Zebulon Baird Vance, Norfolk, Va.; Jefferson Medical College of Philadelphia, 1920; at one time treasurer of the Berkley Machine Works and Foundry Company; treasurer of the Berkley Permanent Building and Loan Association; died Oct. 20, aged 58, of coronary thrombosis.

Kitson, Verner H., Elk Rapids, Mich.; Detroit College of Medicine, 1910; served during World War I; on the staff of the James Decker Munson Hospital in Traverse City, where he died Oct. 22, aged 66, of arteriosclerotic heart disease with coronary occlusion.

Koon, Alpheus Cary, Lakeland, Fla.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1916; died in the Morrell Memorial Hospital Sept. 19, aged 63, of cirrhosis of the liver.

McFarland, Arthur Sidney, Rolla, Mo.; St. Louis College of Physicians and Surgeons, 1906; died in the Phelps County Memorial Hospital Sept. 5, aged 80.

Mantooth, John Thomas ⊕ Melissa, Texas; Chattanooga (Tenn.) Medical College, 1902; past president of the Collin County Medical Society; died in McKinney Aug. 10, aged 77, of complications following a prostatectomy.

Martin, Robert Clarence, Niagara Falls, N. Y.; University of Toronto Faculty of Medicine, Toronto, Canada, 1921; died Aug. 28, aged 60, of coronary occlusion.

Martin, Walter Evans ⊕ Dallas, Texas; Baylor University College of Medicine, Dallas, 1931; member of the American Academy of General Practice; died Oct. 15, aged 56.

Mathisen, George B., Chicago; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; served during World War I; affiliated with Illinois Central Hospital, where he died Nov. 10, aged 78, of chronic glomerulonephritis and multiple myeloma.

Miller, Fred E., Lawrenceville, Ill.; Chicago College of Medicine and Surgery, 1916; died Aug. 24, aged 72.

Mitchell, Edward Dana, Sr. ⊕ Memphis, Tenn.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; fellow of the American College of Surgeons; past president of the Memphis and Shelby County Medical Society; affiliated with Crippled Children's Hospital School, St. Joseph Hospital, and Baptist Memorial Hospital, where he died Oct. 23, aged 77, of heart disease.

Moser, Oran Alexander ⊕ Rocky Hill, Conn.; Yale University School of Medicine, New Haven, 1902; an Associate Fellow of the American Medical Association; past president of the Hartford County Medical Association; for many years health officer of Rocky Hill; formerly affiliated with the State of Connecticut Veterans Home and Hospital; vice-president and director of the Cromwell Savings Bank; died Nov. 10, aged 82.

Nesbit, Wellwood Mack ⊕ Madison, Wis.; Rush Medical College, Chicago, 1917; professor of otolaryngology at University of Wisconsin Medical School; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; affiliated with Madison General Hospital and State of Wisconsin General Hospital; died Oct. 27, aged 63, of coronary thrombosis.

Pasco, George William ⊕ Wolcott, N. Y.; Syracuse University College of Medicine, 1934; past president of the Wayne County Medical Society; died Oct. 30, aged 46, of carcinoma of the liver.

Payne, Edward Albert, Woburn, Mass.; Tufts College Medical School, Boston, 1933; served during World War II; city physician; on the staff of the Choate Memorial Hospital, where he died Oct. 26, aged 43, of coronary disease.

Powell, John Wesley, Sisseton, S. D.; Kentucky School of Medicine, Louisville, 1901; died Sept. 15, aged 78, of nephritis, diabetes mellitus, and cardiac decompensation.

Price, Charles Richard ⊕ Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1930; on the courtesy staff of Miami Valley Hospital, where he died Oct. 23, aged 50, of cardiac arrest due to anesthesia and of mild cardiac hemorrhage due to contusion and multiple fractures of sternum, ribs, and mandible.

Reynolds, Jacob Thomas, Arcadia, Calif.; St. Louis College of Physicians and Surgeons, 1893; died Oct. 26, aged 82, of amyotrophic lateral sclerosis.

Roessly, George Rufus ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1904; died in St. Mary's Hospital Nov. 8, aged 80.

Rush, William Madison, Fern Creek, Ky.; Hospital College of Medicine, Louisville, 1907; served during World War I; died Nov. 3, aged 82.

Schultze, Joseph Henry, Birmingham, Ala.; University of Louisville School of Medicine, 1934; served during World War II; member of the American Trudeau Society; died in Andalusia, Sept. 3, aged 47, of heart failure.

Schumacher, Cyril William ⊕ St. Louis; St. Louis University School of Medicine, 1931; member of the American Academy of General Practice; affiliated with DePaul and St. Mary's hospitals; died Nov. 13, aged 46, of a skull fracture received in a fall.

Senescall, Cleve Ridlon ⊕ Enumclaw, Wash.; University of Illinois College of Medicine, Chicago, 1915; served during World War I; died Oct. 21, aged 64, of coronary disease.

Shipley, John Thomas, Meyersdale, Pa.; Jefferson Medical College of Philadelphia, 1929; served during World War II; died Oct. 26, aged 50.

Siebert, Jacob ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1907; died Oct. 28, aged 66.

Smith, Reuben Menifee ⊕ Stearns, Ky.; Kentucky University Medical Department, Louisville, 1905; died Nov. 2, aged 78.

Thompson, Jesse Eugene, Bristolville, Ohio; Western Reserve University Medical Department, Cleveland, 1904; served during World War I; died Oct. 4, aged 77, of heart disease.

Wagner, Rudolf, Wayne, Mich.; Bennett Medical College, Chicago, 1910; died Oct. 30, aged 79, of hemorrhage into the abdominal cavity and dissecting aneurysm.

DIED WHILE IN MILITARY SERVICE

Coler, Eugene Seeley ⊕ East Hampton, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1922; associate clinical professor of obstetrics and gynecology at Columbia University College of Physicians and Surgeons in New York; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; affiliated with the Southampton (N. Y.) Hospital, Vanderbilt Clinic, and Sloane Hospital for Women in New York; served during World War II; Colonel (MC), U. S. Air Force Reserve; died in England Aug. 30, aged 57, of a heart attack.

FOREIGN LETTERS

BRAZIL

Esophagorespiratory Fistula.—A study on esophagorespiratory fistula was published by Drs. E. S. San Juan, Paulo Freitas, Iseu Costa, and Esmeralda Lomba in *Revista de medicina e cirurgia de São Paulo* (13:277 [June] 1953). The authors collected 42 cases of thoracic crushing injury including two cases of esophagorespiratory fistula. Such cases do not occur frequently, and their prognosis is poor. Dr. San Juan and coworkers described two cases. One patient was treated during the acute period by means of decompressive mediastinotomy and drainage of the pleural cavity. In spite of supplementary measures, the patient did not respond to treatment and died within 24 hours. The other patient survived the acute phase, the esophagotracheal fistula persisting for two months. The treatment used was suture of the esophagus and trachea after a right-sided thoracotomy.

The authors studied the symptoms and signs that appear in both acute and chronic phases, pointing out the difficulties in diagnosing the precise localization of the rupture of the respiratory passages—information necessary before surgical repair is attempted. When the patient does not die as a result of the accident, the lesion may be localized by means of bronchoscopy and esophagoscopy. Rupture of the trachea or of the principal bronchus always takes place in the membranous portion. A contrast examination of the esophagus should be made with iodized oil and controlled by radioscopy, with the patient lying face downward. Communication between the esophagus and the respiratory tract can be made evident in a simpler manner merely by oral administration of methylene blue. The dye will be immediately expelled by coughing if the patient is lying prone. Rupture of the trachea, bronchus, or esophagus, caused by thoracic crushing injury, must be treated without delay because the prognosis is grave. A decompressing mediastinotomy, drainage of the pleural cavity, and administration of oxygen diminish the dyspnea, cyanosis, and hypertensive pneumothorax. Generally, when these measures are taken, emphysema does not develop. Once the acute symptoms have disappeared, only the esophagorespiratory fistula remains. Some authors favor closing the esophageal-tracheal orifice by cauterization. Others, however, recommend surgical closure of the rupture of the esophagus and respiratory tract as the safer method.

Perforated Ulcers of Stomach and Duodenum.—In *Arquivos de cirurgia clinica e experimental,* Drs. Ruy Ferreira Santos, D. Bittencourt, Cassio Montenegro, Ary Carmo Russi, and C. Caricchio reported a study of 302 perforated gastric and duodenal ulcers seen in the emergency ward of the Hospital das Clínicas of the Medical School of the University of São Paulo during a seven year period. Duodenal perforations were more frequent (82.5%) than gastric perforations (17.5%). Eighty-one per cent of the patients were in the third, fourth, and fifth decades of life. The patients in their twenties predominated. Their ages ranged from 15 to 78 years (average 35.1). As a rule, the onset of duodenal ulcers and also perforation occurs at an earlier age than of gastric ulcers. There was a higher proportion of ulcers and their perforations in men than in women. Perforated ulcers occurred oftener during spring and autumn.

The percentage distribution of the perforations through the 24 hours of the day showed that the duodenal ulcers perforated oftener in the morning, before breakfast, and that the gastric ulcers are more apt to perforate in the evening and during the night, in the periods of digestive activity. Only 10.6% of the patients had not had epigastric pain, pyrosis, nausea, or vomiting in the past. Bleeding and other digestive symptoms were reported less frequently.

In this series the preponderant symptom of perforation was a sudden sharp pain in the epigastrium, radiating to the lower right abdominal quadrant or to the right shoulder. Reflex vomiting was common. Peritoneal irritation was manifested in 93% of the patients by rigidity of the abdominal wall. Paralytic ileus was rare, probably because of the early admission to the hospital. Six per cent of the patients came to the hospital later and had severe peritonitis with meteorism, a dull percussion note in the flanks, and bulging of the pouch of Douglas. The liver dulness disappeared in 62%. Since the roentgenological examination at various angles revealed free gas in the peritoneal cavity in only 77%, the absence of roentgenological signs of pneumoperitoneum does not rule out a perforated ulcer and, in such a case, the diagnosis must depend chiefly on the history and physical findings. Absence of pneumoperitoneum does not always mean there is a sealed perforation, but this diagnosis is very likely when there is free gas in the peritoneal cavity and improvement of the abdominal rigidity. Hydropneumoperitoneum indicates diffuse and severe peritonitis. Deterioration of the general condition of the patient was more frequently observed in the patients with gastric than in those with duodenal perforation.

The mean elapsed time from the moment of perforation until admission to the hospital was 11.4 hours. A wrong diagnosis was made 13 times, consisting of acute appendicitis in 11 patients, acute cholecystitis in one and acute abdominal condition, cause undetermined, in one.

Suturing operations were performed in 47 patients in this series, including simple suturing in 20, suturing plus epiploplasty in 23, suturing plus gastroenterostomy in 3, and suturing after selective resection of the ulcer in one. Resections were performed in 252 patients; the anastomosis was antecolic in 167 and retrocolic in the rest. The authors prefer gastroduodenal resection because: (1) the suturing operations are not always curative, and in many patients the ulcer persists and a second operation must be performed (40 to 65% according to the literature; 22.7% in this series); (2) resection prevents recurring perforations (only one recurred in this series); (3) resection eliminates the possibility of multiple ulcers and the danger of not recognizing multiple simultaneous perforations (one patient in this series had multiple perforations); (4) resection prevents a stenosis and postoperative bleeding and takes into consideration the possibility of the perforation being associated with a gastric malignancy; and (5) the operative mortality following resection is low.

The criterion for selecting the palliative or the radical operation is the evaluation of the patient's age, the elapsed time after the perforation, the patient's general condition, and the peritoneal reaction observed during laparotomy. Drainage was used in 20 of the resections to prevent or treat diffuse peritonitis. It was indicated when the general condition of the patient or some technical accident led to fear of an eventual leakage around the sutures. Inhalation anesthesia or subarachnoidal spinal anesthesia was used, according to the preference of the surgical teams. As a rule, spinal anesthesia was not used when the general condition of the patient was poor or when too many hours had elapsed since the perforation.

The duration of hospitalization of the surviving cases was taken as a quantitative index of the complications. It appeared to depend on the elapsed time between perforation and treatment and on the patient's age rather than on the duration of the operation. On the average, the patients with gastric perforation, those treated by palliative suturing, those in whom drainage was necessary, and those who were given inhalation anesthesia remained in the hospital for longer periods, but it must be remembered that, as a rule, all such patients were

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

admitted in poor general condition. Postoperative complications developed in 49 patients.

Further treatment, including radical surgery, was needed in 22.7% of the surviving patients treated by suturing and who answered a follow-up questionnaire. Although the follow-up studies are not complete, the patients treated by resection were cured. A few patients had mild sequelae following gastrectomy.

Intestinal Schistosomiasis as an Occupational Disease.—Dr. Samuel Pessoa, São Paulo State University, reported to the Associação Paulista de Medicina a study on 18 patients with intestinal schistosomiasis among employees of the National Malaria Service who clean the sanitation ditches at Aracajú, Sergipe, without wearing boots. Under these conditions, they are subjected to continuous heavy infestations by cercariae of Schistosoma mansoni. These workers have very high incidences of allergic and toxic phenomena and cirrhosis, anemia, a high erythrocyte sedimentation rate, and eosinophilia are more marked in them than in other victims living in the vicinity. Bronchial manifestations are observed in the severer cases; they are frequently diagnosed as bronchitis and are due to the direct effect of the parasites or to circulatory alterations. The author pointed out that the high sedimentation rates are probably due to hepatic lesions, and he believes the fever, present in severer and older cases of the disease, to be caused by an allergic mechanism.

CHILE

Seventh Medicosurgical Meeting of Valparaiso.—The transactions of the seventh medicosurgical meeting of Valparaiso appeared in the March issue of the quarterly of the Valparaiso Medical Association. Leukemia, primary cancer of the lung, and antibiotics were discussed.

Leukemia.—Dr. Etcheverry stated that there are three approaches to the pathogenesis of leukemia: the infectious, the neoplastic, and the one that considers leukemia a disease of adaptation. After analyzing each of these, the author inclined to the belief that the leukemic cell, because of its immaturity and malignant character, has much in common with the neoplastic cell. The symptoms and clinical course were described by Dr. Raul Cabrera. In a series of patients with acute myeoblastic leukemia, 40% had splenomegaly and 70% had hepatomegaly. Involvement of the lymph glands was noted in 34%, and in 81% of these the involvement was limited to the cervical nodes. Pallor of the skin and mucosa was present in all the patients and was parallel with the degree and with the evolution of the anemia. Leukamid was present in 12%. Nearly 40% had temperatures that fluctuated between 99.5 F and 101.3 F, and 21% had temperatures between 102.2 F and 104 F. Purpuric manifestations were present in 46%, epistaxis in 59%, pyorrhea in 59%, and metrorrhagia in 15%. Palpitation on exertion was common, and a soft systolic murmur at the apex was present in 4% of the patients. Respiratory symptoms were rare. Anorexia or diarrhea or both occurred in 25%, arthralgias in 15%, and neurological signs in 28%. In a series of patients with acute lymphoblastic leukemia, splenomegaly was present in 83% and hepatomegaly in 40%. The lymphatic system was frequently involved. Pallor of the skin and mucosa was present in all the patients, and 87% had a febrile course.

In a group of patients with chronic myeloid leukemia, splenomegaly was present in 60% and hepatomegaly in 95%. Hemorrhages occurred in 4.6%. Although lymph glands were frequently involved, myeloid metaplasia was present in only 7.6%. Pallor of the skin was present in 85%, moderate fever in 61%, and neurological signs in 10%. In a series of patients with chronic lymphatic leukemia, splenomegaly was present in all the patients and hepatomegaly in 76%. A moderate irregular fever was noted in 28%.

Dr. Garreton and associates discussed the incidence of leukemia in Chile, which in the hospital population varies between 0.22 per thousand and 0.38 per thousand. An increase in prevalence was noted between 1940 and 1947. In children 94% of the cases were of acute leukemia. The chronic type is observed much more frequently in men than in women. The death rate from leukemia was 0.33 per thousand in 1940 and 1.05 per thousand in 1951.

Cancer of the Lung.—Drs. H. Apablaza and C. Palma reviewed 6,161 autopsies performed in the Van Buren hospital of Valparaiso between 1936 and 1951 and found that primary cancer of the lung was second in frequency only to cancer of the stomach. The right lung was more frequently the site of neoplasm than the left. Dr. Olivares and co-workers of the Salvador Hospital of Santiago reviewed 21,642 hospital admissions between 1942 and 1949 and found that, of all cancers, gastric neoplasms accounted for 48%; cancer of the esophagus for 8%; cancer of the biliary tract for 6%; and primary cancer of the lung for only 3%. Dr. Fritis and co-workers presented statistics showing that 60% of the primary cancers of the lung were of the undifferentiated type; 20% were of the epidermoid type; 14% were adenocarcinomas; and 3% were of the alveolar type.

The value of signs and symptoms in the diagnosis of cancer of the lung was discussed by Dr. Lucchini and associates. They concluded that most patients come to the physicians too late, mainly because the symptoms in the beginning are vague and not severe. Dr. Salvestrini and co-workers spoke of the use of radiology in the diagnosis of cancer of the lung. In all of the 105 cases described, radiological signs of cancer were present, but the interpretation was erroneous in 80 cases. This high percentage of error is due mainly to the fact that the cancer gave direct radiological evidence of a small tumor in only 26, whereas only indirect signs were present in 79 patients. Dr. H. Dew of Australia stated that in his country the radiologist makes the diagnosis in 30% of the cases. The main value of the roentgenogram is that it is often the source of our first suspicion of cancer of the lung. If every patient with a thickened shadow in the center of the lung is considered to have cancer until it is proved otherwise, the percentage of positive diagnoses should greatly increase.

Dr. G. Zamorano and associates of Valparaiso obtained negative results from bronchoscopy in 42% of the patients with cancer of the lung in whom bronchoscopy was performed, but they maintain that nevertheless this simple technique should always be used in patients suspected of having cancer of the lung. Dr. H. Dew of Australia stressed the fact that the use of bronchoscopy, roentgenograms, and biopsies can give a positive diagnosis in almost 80% of all cases.

Dr. R. Eulufi presented statistics on cytological diagnosis. In 41 patients with proved cancer of the lung, neoplastic cells were found in only 6, and he concluded that the value of this method is great when the findings are positive but that negative findings are valid only if they are repeated five or six times.

Antibiotics.—Dr. A. Vargas Carretero and associates observed 94 patients (73 of whom died) with subacute endocarditis between January, 1947, and June, 1952. The average age of the patients who survived was 27.4 years and of those who died 41.2 years. Of those who died, 37 received no antibiotic treatment, because the diagnosis was not made and the remaining 36 died during the treatment. The authors stressed that a favorable result can be expected in 54% of the patients if the treatment is started early and in only 25% if the treatment is started later than three months after the onset. Of 56 patients who were not treated with antibiotics because a correct diagnosis was not made, 93% died within six months and the rest within one year. Of a group who were treated with antibiotics, 77% died within six months and 3.8% survived for more than two years. Anatomical changes are another means of studying the effects of antibiotic treatment. The heart valves of patients who had been treated but had died of subacute endocarditis showed at autopsy various degrees of healing. The average spleen weight in patients without treatment was 324 gm., and in those who had a full course of treatment 272 gm. Another important finding was that well-conducted treatment prevents nephritis.

Antiparasite Campaigns in Chile.—Prophylactic activities against hydatidosis have continued in the province of Valdivia. A. Hube found Taenia echinococcus in 19 of 434 dogs. A total of 4,012 dogs were given arecoline hydrobromide. This was accompanied by an educational campaign in 43 schools. Movies dealing with hydatidosis were shown to more than 30,000 persons in small villages. More than 6,000 people were treated between February and May, 1953. In the period of January to March, the staff of the department of parasitology examined 2,691 persons in Lanco, Malalhue, and Panguipulli. Of 2,166 Ghedini-Weimber reactions, 70 were positive, and, of the same number of Casoni intradermal reactions, 169 were positive. The new reaction of conditional hemolysis, which was first used in Chile by Negme, Naquira, and Tagle, was performed on 2,186 persons and was positive in 133. A mobile x-ray unit permitted the study of pulmonary hydatidosis. In order to evaluate the results of the educational campaign, a survey was conducted in Malahue that revealed that 80% of the population knew how to dispose of the organs of cattle with hydatidosis, whereas prior to the campaign 90% of the population did not know.

After the diagnosis of the first acute cases of American trypanosomiasis (Chagas' disease) made by Drs. G. Gasic, R. Gajardo, and A. Neghme of the department of parasitology, a survey of all the country was started to determine the importance of infection by Trypanosoma cruzi. With this in mind, the department undertook to define the endemic areas, and in these areas infestation with Triatoma infestans was studied. The xenodiagnostic method was used to determine infection by T. cruzi. Since 1944 a total of 25,919 xenodiagnoses were made on persons living in endemic zones, with positive results in 8.7%. In addition to this, 6,256 domestic animals were examined and 8.1% were found to be infected. Most persons infected with T. cruzi were asymptomatic carriers; others had myocarditis.

Availability of Food in Chile.—The department of foodstuffs of the National Health Service has for the last 15 years been making a survey of availability in order to determine the exact state of the diet of the population. Drs. A. Riquelme and M. Garcia B. have recently completed a report on this subject covering the years 1947-1951. The average per capita distribution of foodstuffs was calculated by adding to the national production all imported foodstuffs and subtracting that which was exported. The population of the country was fixed at 6 million according to the latest census. As compared to the per capita per year figures for 1926 (based on the population of Santiago only), the milk supply increased from 36 to 102 liters; fish and other sea foods from 8 to 10.3 kg.; citrus fruits from 4.5 (in 1941) to 9.2 kg.; vegetables from 18.25 to 60 kg.; and sugar from 20 to 28 kg. There was no change in the figures for eggs (37.4), potatoes (75 kg.), and cereals (170 kg.). The figures for meat dropped from 73 to 31 kg.; for legumes from 15.3 to 6.6 kg. (mainly due to an increase in export); and for fats from 14.6 to 6.4 kg.

At the fifth annual meeting of the Chilean Society of Nutrition, Dietetics, and Toxicology held in December, 1948, a list of foodstuffs was drawn up that was to be the goal that must be attained in the nutritional plan of the country. Expressing the results in percentages of deficit or overproduction, the report noted a deficit of 70% for meat; 65% for legumes; 42% for potatoes; 46% for other vegetables; 65% for eggs; 49% for citrus fruits; 42% for fats; 33% for milk; and 14% for fish and other sea foods. There was an excess of 86% for sugar; 20% for cereals; and 6% for other than citrus fruits. The report further compares the nutritional values in the chart that they obtained with the one recommended by the National Research Council of the United States and obtained the following figures (expressed in percentage of deficit): for calcium, 52%; for riboflavin, 45%; for thiamine, 37%; for niacin, 36%; for caloric value, 30%; for ascorbic acid, 28.4%; for iron, 27%; for vitamin A, 10%; and for proteins, 14.3%. In conclusion means for remedying the situation, on both a short and long term basis, were proposed.

LONDON

Smog.—The smog that devastated London last December continues to be a subject of topical interest. Everyone has his remedy for it, and investigations are being carried out at all levels from the government downward. In the medical sphere it has been responsible for an interesting tiff between the general practitioners of London and the Ministry of Health, in which the Ministry has come off best. Toward the end of October the local Medical Committee for the County of London, a statutory body set up under the National Health Service to represent the 6,000 physicians in Greater London, issued a statement to the press calling for immediate action by the government to prevent a repetition of the disaster, and advising the wearing of gauze masks, comparable to those worn by surgeons, should there be a recurrence. The results were a rush on pharmacies the next day for gauze to make homemade masks—at a time when there was a shortage of gauze in the country—and an official statement from the Ministry of Health.

This was a carefully reasoned statement pointing out that there was some danger that the public might take the suggestion as being too easy a solution, and indicating that it was necessary to distinguish between ordinary persons who are not ill and those suffering from weakness of the heart and lungs. In the case of the former a simple gauze mask might help, but such a mask has certain obvious difficulties, since it is intended primarily to prevent spray from going outwards from the mouth and nose and not to prevent the intake of noxious substances. The statement went on to point out that there are simple masks widely used in industry that are more effective than the surgeon's gauze mask and are available commercially at little cost. Other practical measures are probably quite as effective as the surgeon's gauze mask and can be produced in the home, such as a scarf or towel or other cloth worn round the face. In the case of patients with pulmonary or cardiac disease, the problems are much more difficult, as the more efficient the mask the more difficult would it make the breathing. Such patients should be advised to stay at home during a thick fog, since fog is always less dense indoors than out. The statement added that the Ministry was actively investigating the problem.

The results of its activities have now been announced by the Minister of Health as follows: "I am advised that . . . . no mask which people could be expected to wear for long periods is likely to give complete protection, but that there are certain types of masks which may give some help to those most likely to be affected by smoke-polluted fog—namely people suffering from existing disease of the heart or lungs. I am, therefore, proposing to enable doctors, if they feel it to be desirable in each individual case, to prescribe under the National Health Service certain specified types of masks for patients suffering from these conditions who live or work in an area where smoke-polluted fog is likely to occur." Two types of masks are to be made available: one with a semirigid frame capable of being molded to the face and one fastened by tapes, of a type usually worn by surgeons. Both will incorporate removable pads of thin gauze and cotton tissue.

Thus ends an episode that should show the general practitioners the dangers of unskilled public relations. A little more contact with the Ministry of Health might have saved them a great deal of discomfiture. An editorial in *Lancet* (2:976 [Nov. 7] 1953) stated, "A gauze mask or a woollen scarf could be expected to exclude a reasonable proportion—perhaps a half to three-quarters of the particles, which might be enough to bring the pollution of inhaled air below the margin of danger. *Complete purification is . . . too much to hope for.* The more layers of gauze used, the more efficient the mask will be; but a balance will have to be struck between efficiency and resistance to breathing. The scarf or mask will serve a second purpose, warming and humidifying the incoming air . . . A gauze mask or, possibly better, a thick woollen scarf wrapped round the face, by excluding droplets and by warming and scrubbing the inhaled air, may, so far as can be judged, really prove useful. The only . . . danger seems to be too great a respiratory resistance in a patient already breathing with difficulty. Possibly, . . . warming the air is as important as filter-ing it. A bronchitic's room should . . . be well heated, even if he cannot wear a mask; . . . the method of heating should not entail sucking in more fog from outside; electric radiators are *particularly suitable*."

BCG Vaccination.—In 1949, official permission for the use of BCG vaccine was first given in this country for nurses and medical staffs in hospitals and (at the discretion of chest physicians) for the close home contacts of tuberculous patients. The Medical Research Council is also carrying out an extensive controlled trial among persons leaving school. The Minister of Health has now announced that he is prepared to approve plans for giving BCG vaccination to children before they leave school. Vaccination should be carried out by designated medical officers on the responsibility of the medical officer of health. It is to be given to children during and, if possible, toward the end of the year preceding their 14th birthday. This means that the child will be at school for at least another year before leaving and will therefore be under supervision. Parental permission must be obtained in writing before vaccination.

This announcement has come as a surprise to many, in view of the conservative attitude of the Ministry of Health's advisors on the subject. Cause for such surprise is, however, greatly diminished on reading the accompanying memorandum on the subject, which so damns the process with faint praise that he will be a brave medical officer of health who will take advantage of this new dispensation. As typical of the official attitude of Great Britain on BCG vaccination, a few extracts from this memorandum may be of interest. It starts off with the dogmatic statement that despite the vast number of vaccinations that have been performed with either liquid or lyophilized vaccine during the past 20 years, there is no scientific evidence of its value. On the other hand, it is conceded that "from the work that has already been done on the vaccine it can be generally assumed that the preparation, in the doses usually prescribed, is harmless. It may also be reasonably accepted from trials abroad that the vaccine confers some degree of protection against the first infection with virulent M. tuberculosis. It is, therefore, probable that vaccination will lower the incidence of active primary tuberculosis in its various clinical manifestations, in particular, such forms as meningitis, miliary tuberculosis and primary tuberculous pleurisy. There is much less conclusive evidence that vaccination protects against subsequent super- or reinfection, although there are observers who believe that the development of postprimary tuberculosis is rendered less severe by inoculation. There is no absolute scientific proof in countries where the vaccine has been extensively used over many years that the fall in the tuberculosis mortality figures is due to BCG. In a number of countries where no BCG has been used there has been an equally rapid decrease in the number of deaths from tuberculosis. There are some who claim that BCG vaccination confers no benefit upon the individual and that all the apparent improvement in the incidence and mortality figures following mass vaccination is due to the collateral influence of other factors, such as the increased medical observation and improved living conditions and selective sampling. It is possible that those vaccinated are already a selected group, as an unknown number of the positive reactors of the population has already developed active disease. The most susceptible have therefore already been removed from the material under survey."

It is considered "unwise at this stage to extend the scheme generally to newborn infants: first, because it is in many instances unnecessary; secondly, because BCG vaccination removes completely the value of the tuberculin test in diagnosis; thirdly, because in the absence of subsequent infection the post-vaccination tuberculin sensitivity tends to wane and eventually disappear so that re-testing at frequent periods is necessary, and fourthly, because the complication rate is higher in newborn infants than in the older age groups, probably due to the greater difficulty in performing the intradermal injection and the slow development of the defensive mechanism."

It is recommended that two prevaccination intradermal tuberculin tests should be carried out, using purified protein derivative (Seibert), 0.00002 mg. (0.1 ml. of tuberculin) and 0.0002 mg. (0.2 ml. of tuberculin). The liquid vaccine is obtained from the State Serum Institute, Copenhagen. For some reason it is not made in this country. As the National Association for the Prevention of Tuberculosis points out in its annual report, "This seems astonishing when it is realized that the vaccine is produced in Canada, the U. S. A., India, Ceylon, Australia, Singapore, Indonesia, Turkey, China, Japan, three South American countries, the U. S. S. R., and at least ten European countries."

Vaccination is to be carried out by strictly intradermal injection. As a general rule, segregation of school children is not considered necessary, except when the child is living in close contact with a person with infectious tuberculosis. There is considered to be no need to make roentgenograms of vaccinated children routinely unless complications develop. Constitutional reactions are stated to be extremely rare, and the incidence of local reactions is put at 0.3%.

Plea for Decentralization of Hospital Control.—In a memorandum prepared for the Hospital Discussion Group by a working party of hospital administrators and published in *Lancet* (2: 1035, 1953), a plea is made for increased decentralization in the control of hospitals under the National Health Service. As an example of the present excessive degree of decentralization, attention is drawn to the fact that between July, 1948, and the end of 1952, the total number of circulars issued by the Ministry of Health was 656 to regional hospital boards, 583 to hospital management committees, and 598 to boards of governors of teaching hospitals. This is about one circular every three days to every hospital in the country. As the memorandum comments: "Few will deny that 'The formulation of policy in its major features' is the proper function of the Ministry, but is it essential for the Ministry (as opposed to a regional board or management committee) to issue detailed guidance on such matters as supply of razorblades to patients, issue of sweets to children, provision of telephones for hospital staff, washing-down of walls and paintwork, and detailed control of establishments? Complete standardization on such matters, and on many others, makes for administrative convenience and tidiness at the expense of individual judgment, initiative, and responsibility. Detailed control and advices on these aspects of hospital life could safely and more satisfactorily be left to the individual authorities or their officers."

In the financial field, centralized control in its present form is considered "generally reasonable," but a plea is made for a system of five-year grants for building maintenance and capital expenditure. Strong exception is taken to the attempted application of civil service methods to hospital administration. "What appears to cause both difficulty and antagonism at the present time is the tendency for the Civil Servant to apply to every level of the hospital service the methods of impersonal administration that are suitable for the central functions of the Ministry, but not for the day-to-day management of individual hospitals or hospital groups." An appeal is also made for a greater degree of delegation of power from the regional hospital boards to hospital management committees. There must be a certain amount of central control by the regional boards, but "it should be the policy to give to the management committees as much freedom as possible and to avoid interference in the details of day-to-day administration."

Tuberculosis in Scotland.—A depressing picture of the prevalence of tuberculosis in Scotland is given in the 39th annual report (1952-53) of the Royal Victoria Hospital Tuberlosis Trust for the Care and Prevention of Tuberculosis throughout Scotland. The mortality figures as a whole are favorable. In 1952 the death rate from respiratory tuberculosis was 27 per 100,000 of the population, and from nonrespiratory tuberculosis 5 per 100,000, giving a mortality from all forms of the disease of 32 per 100,000, which is the lowest figure on record. Nevertheless "there is a much more sinister side to the problem of respiratory tuberculosis." The death rate from tuberculosis of the lungs in young men from 15 to 24 is half as much again as it is in England, and the mortality among young women in this age-group is twice as high. The position in relation to new cases is also very disquieting. The provisional figure for cases of respiratory tuberculosis reported in 1952 was 7,259, compared with 7,776 in 1951 and 8,653 in 1949. The annual number of notifications, though falling, is still over 60% higher than it was in 1936. Half of the new cases are among young persons. The situation is even worse than the provisional figures suggest, because in 1936, only 74% of the notifications were subsequently confirmed, whereas in 1951, 97% were confirmed. It is estimated that the increase in new cases between 1936 and 1951 is about 110%. The contribution of cases found by mass miniature radiography to this increase is considered to be insignificant compared with the number found in routine medical practice.

"The Committee, therefore, wish to state again with all the emphasis they can command that the publicising each year of overall death-rate figure which is stated to be yet another low record for tuberculosis does a public disservice, since it creates in the mind of the people the erroneous impression that tuberculosis is 'on the run.' The information that the annual number of confirmed new cases and the total number of known sufferers are over twice what they were before the war receives less publicity. The fact that in Scotland the statistics are worse than in most countries of Europe from which reliable figures are available is little appreciated."

Actinomycosis in Scotland.—According to I. A. Porter (*Brit. M. J.* 2:1084, 1953) a survey of hospital records revealed the occurrence of 186 cases of actinomycosis in Scotland during the 13 years from 1936 to 1948. A total of 98 patients came from the northeast of Scotland, which is predominantly agricultural and has a population of 444,000. The remaining 88 patients came from the rest of Scotland, which has a population of 4,398,000. There was no significant difference in the rate of attack between residents in the large towns and residents in the small towns and rural areas in the northeast area, but in the rest of the country there was a significantly higher attack rate in the smaller towns and rural areas than in the large towns. Of the 173 patients whose occupations were known, 39 were in agriculture—a higher incidence than that of any other occupation. The ratio per 100,000 for male agricultural workers was 146 in the northeast area, 29 in the rest of the country, and 50 for the entire country. The comparable figures for nonagricultural workers were 33, 3.3, and 5.2. Just over half the cases (94) were in the 10 to 29 age-group, and 78% of the patients were male. The cervicofacial region was most commonly affected (65%), followed by the abdominal region (19%). In 22 instances the disease appeared in the cervicofacial region following dental extraction, and in another 33 patients carious teeth were noted. In 23 of the abdominal cases there was a history of an associated appendectomy, and in two of an appendiceal abscess.

Hospital Independence.—Mr. Macleod, Minister of Health, announced that he has asked the committee inquiring into the cost of the National Health Service to consider a new method of financing state hospitals. The method is a block grant system similar to that used for universities. If such a change were approved by Parliament, hospitals would gain much in independence and freedom. At present yearly estimates must be sent to the Ministry of Health, which can and does reduce them. Any unspent balance at the end of the fiscal year may not be carried forward. This form of financing, with ultimate control vested in the Ministry, imposes a rigid pattern on hospital planning and expenditure.

If block grants covering a number of years, made by a body resembling the University Grants Committee, were substituted, hospitals would be freed of direct government interference. They would also enjoy more latitude in planning and incurring expenditure. Mr. Macleod, in making his announcement, confessed that he had not made up his mind on methods of financing.

New Cancer Research Laboratories.—The Imperial Cancer Research Fund was founded in 1902, under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. It was one of the first organizations to undertake experimental research in its own laboratories. It first occupied rooms in the Royal College of Surgeons. Its scope and activities gradually extended until, in 1939, a block of modern laboratories was built and opened at Mill Hill on the northern side of London. In 1951, the council of the fund decided to foster and support special investigations on outstanding problems of cancer in human pathology. Since the subjects chosen for investigation were closely related to the surgical treatment of human cancer, it was decided that this work should be begun in the pathology department of the Royal College of Surgeons. Under the direction of Prof. G. Hadfield, the work expanded rapidly, and additional space was provided by renting from the Royal College of Surgeons the house at no. 48, Lincoln's Inn Fields. The new laboratories were officially opened on Nov. 10 by Prof. H. R. Dean of Cambridge, the dean of English pathology and chairman of the council of the fund. The work will be integrated with the experimental work done at the Mill Hill laboratories under the direction of Dr. James Craigie and with observations made on clinical material from the London teaching hospitals.

MEXICO

Leprosy in Mexico.—Although not comparable in importance to tuberculosis and malaria, leprosy is still a public health problem in Mexico. For that reason the Department of Public Health and Assistance has a special organization to fight this disease, called the National Campaign Against Leprosy. Some of its activities, as well as other facts concerning leprosy in Mexico, were pointed out recently by Dr. Roberto Núñez Andrade, in the *Gaceta Médica de México* (83:5, 1953).

Before the arrival of Spanish conquerors leprosy did not exist in Mexico. It is likely that it was brought in by the conquerors and by African and Antillean Negro slaves in the early part of the 16th century, when it first was recognized in the Yucatán península. Travelers from the Philippine Islands, Japan, and China spread leprosy along the Pacific coast.

The number of patients with leprosy officially registered at the National Campaign Against Leprosy offices up to Dec. 31, 1952, was 11,087. The highest leprosy rate is found in the state of Colima, with 310.8 patients per 100,000 population. The rate for Mexico as a whole is 40.7 per 100,000.

Many regions in the country have not been intensively surveyed yet, and there is sometimes a disinclination to give information to health officers. It is conceivable that there are over 50,000 persons with leprosy in Mexico. About 66% have the lepromatous type; about 20% the tuberculoid; and the type of the remaining 14% is undetermined. Ninety per cent of the patients are adults. The disease is rare in persons of pure white or pure Indian blood; 98% of persons with leprosy are "mestizos." Almost 100% of the patients are classed as poor. Most of the registered male patients are farmers, city workers, or clerks, and most of the female patients are engaged in housework.

The National Campaign Against Leprosy has a leprosarium, 4 special wards in general hospitals, and 19 dispensaries for treating the disease. Through these facilities it has been possible to isolate 3.6% of the patients in the leprosarium and 1.3% in the wards. Specific treatment with the sulfones has been carried out in 13.7% of the patients, and 0.06% have been released at its completion. Private contribution has added three segregation homes, which house about 60 healthy children separated from their parents since birth. There is still a high death rate among the patients from such causes as generalized dissemination of the disease, cachexia, enterocolitis, lobar pneumonia, nephritis, cardiac insufficiency, pulmonary tuberculosis, edema of larynx, and cancer.

National Congress for the Protection of Children.—The first National Congress for the Protection of Children was held at Mexico City, Aug. 9 to 15. It was organized by the Department of Public Health and Assistance and sponsored by the President of the Republic. The main purpose of the congress was to draft a federal code for the protection of children. The present status of the law protecting children in Mexico, children's social medical care, educational protection, child labor, and the care of disabled children were among the problems discussed.

SWEDEN

Intoxicated Motorists and Pedestrians.—In 1949 a government committee was appointed to investigate the part alcohol plays in causing traffic accidents. The committee undertook a statistical study of the persons convicted of driving under the influence of alcohol between July 1, 1948, and June 30, 1949. Much other material was studied, and recommendations were made with a view to reducing such accidents. These recommendations reflect the committee's desire to tighten up already existing regulations. It was argued that the concentration of alcohol in the blood should be investigated not only in motorists but also in bicyclists, drivers of horse-drawn vehicles, railway engines, trams, ships, and airplanes, and other persons dealing with such vehicles. A concentration of alcohol in the blood as low as 0.05% should count in weighing evidence against suspects, and the police should have the right to test a driver's sobriety by measuring his expired breath by means of the so-called drunkometer.

Having been invited to comment on the recommendations of this committee, the Swedish Medical Association expressed grave doubts regarding the 0.05% level of blood alcohol, for it is doubtful if what is called the criminalization of persons showing this level will contribute to greater traffic security. In view of the American investigations (Holcomb's) and other observations, the level should be raised to 0.1%; on the other hand, it would be well for responsibility for traffic accidents to be extended to the pedestrian whose consumption of alcohol may have contributed to them. All persons involved in traffic accidents, including the driver of a push bicycle, should come under the same law in respect to alcohol consumption. Use of the drunkometer by the police should not be extended to an attempted estimate of the degree of the effect of alcohol but should be limited to determining the presence or absence of alcohol in the breath. The Swedish Medical Association also recommends further study of the factors contributing to traffic accidents.

Legal Abortion Statistics.—The government committee appointed in 1950 to study the problems of abortion, legal and illegal, issued a memorandum on the subject in September. In his comments on this memorandum in the organ of the Swedish Medical Association, *Svenska Läkartidningen,* Dr. Gunnar Berg quotes some impressive figures. The new law of 1938 concerned with legal abortions was not reflected in a marked rise of their number till 1943, when they numbered 703. There was a marked rise in the following years, and it culminated in 1951 with 6,328 or 58 legal abortions per 1,000 parturients. This number fell to 5,322 in 1952, and the figure for the first quarter of 1953 was smaller than that for the first quarter of 1952. This fall appears to reflect an increased tendency on the part of the medical authorities to reject applications for legal abortion, for in 1949 only about 13% of these applications were rejected, whereas the corresponding figure for 1951 was about 16% and for 1952 about 21%. In the same period there has been a fall in the total number of applications, from 6,884 in 1951 to 6,201 in 1952. Spontaneous or illegal abortion occurred among 21.9% of the 759 women whose applications for legal abortion in 1947 and 1949 were refused.

It is remarkable how greatly the indications for legal abortion have varied between 1940 and 1950. In 1940 as great a proportion as 71.9% of the indications for legal abortion was disease or some bodily ailment, while the corresponding figure for 1950 was down to 30.2%. Eugenic indications fell from 23.7 to 9.2% in the same period and humanitarian indications from 1 to 0.3%. On the other hand, weakness or general debility was an indication for legal abortion in only 3.4% of the applicants in 1940, whereas the corresponding figure for 1950 was 50.7%. Certain general principles seem, however, to be gaining general credence, and in the above-mentioned memorandum there is a recommendation for the obligatory adoption of sex education in all the schools and free medical advice on contraception. It is noted that knowledge of the qualitative merits of contraceptives has not advanced in pace with the gains made by medical research in other fields. The public authorities, therefore, would do well to provide the means for further scientific research concerning contraceptives.

The Prognosis for Lobotomy.—At the Lillhagen Hospital, Gothenburg, lobotomy has been undertaken on so many patients since 1946 that it is now possible to calculate approximately the ultimate prognosis for the patients operated on. In 1951, Dr. Sven Foltmann published a preliminary report on the first 100 women patients operated on between 1946 and 1950. In *Nordisk Medicin* for Oct. 15, 1953, he has brought his figures up to date and has shown how necessary it is to allow an observation period of some years before evaluating the final results. After withdrawing 3 cases for various reasons, he follows the fate of the remaining 97 bilateral cases, 55 of which were operated on according to the Freeman and Watt technique and 42 according to the Lyerlys technique. There were 71 cases of schizophrenia and 22 cases of psychopathy. The psychopaths fared better than the schizophrenics, the former including 19 patients with some improvement and only 3 who were not improved. The schizophrenics included 18 patients who were not improved. Although the prognosis became worse with the length of hospital treatment in the schizophrenic group, this time factor was of no great importance in the psychopathic group. The length of the interval between the first appearance of symptoms and the lobotomy averaged 13 years (range 1½ to 32 years). The interval between admission to hospital and the lobotomy averaged 7½ years. The patient's age was not found to influence the prognosis.

With an observation period of 2 to 7 years after the lobotomy Foltmann admits worse results than those of his preliminary report. Eleven patients who had been discharged from the hospital had to be readmitted because of relapse. The six psychopaths readmitted could be discharged again after 2 to 13 weeks with almost as much improvement as on their first postoperative discharge, but the five schizophrenics who were readmitted to the hospital because of relapse fared much worse, since they were no better than they had been before the operation and had to be retained in hospital in spite of shock treatment. Foltmann also concludes that a study of the premorbid personality of candidates for lobotomy may prove helpful in forming a prognosis. He also describes an amnesic-anosognosic syndrome that may be the outcome of lobotomy.

Plastic Dressings for Burns and Operative Wounds.—Since the autumn of 1952, Dr. Bertil Olow and Dr. Karl-Erik Hogeman have been testing plastic dressings for burns at the University Hospital in Malmö. By painting or spraying a plastic solution they have succeeded in covering burns with a thin transparent film that adheres to the surrounding intact skin but not to the burn itself. This film has remained adherent to the intact skin for up to 15 days, and meanwhile the healing processes of the sterile burn can be watched daily through the film. These tests are still in a preliminary stage, and hitherto the ability of a film to keep its place over a joint about which there is some movement has not been satisfactory. Experiments are, therefore, being continued in this connection and also in view of any possible toxicity that the constituent elements of the film may present. Dr. Elis Lewin of Gothenburg has experimented since 1947 with plastic dressings for operative wounds. After the usual preoperative treatment of the patient's skin, he paints it with a plastic solution that is also applied to a plastic film of suitable size. After about 30 seconds, when the plastic solution has dried, the transparent film is applied to the skin and becomes firmly adherent. At the completion of a laparotomy, sutures of the skin can be carried through this film if necessary, but it also can be easily removed. A new application of the plastic solution can also be made after the abdominal wall has been sutured, but as yet this easy method of applying a dressing has not been widely adopted.

CORRESPONDENCE

SURGICAL SURVIVAL

To the Editor:—The editorial in the Oct. 24, 1953, issue of THE JOURNAL, "Surgical Survival of the Young and of the Aged," contains a passage that states that elderly patients are more susceptible to anoxia than young patients. This statement is open to debate.

Experiments of German investigators (Rüff, S.: Grundriss der Luftfahrtmedizin, Leipzig, 1944, J. A. Barth, p. 94) in the medium of low pressure chambers, in combination with graduated exercise tests within them, showed that tolerance to oxygen want uniformly increases, that is, susceptibility to anoxia decreases with advancing age. As previously stated (May, S. H.: Air Travel and the Cardiac Patient, *Am. Heart J.* **40**:363, 1950), this should not be too surprising. Variations in oxygen tension and acid-base equilibrium of the blood are chiefly controlled by the chemoreceptor fibers in the aortic and carotid bodies. It must be thought that the challenge to these nerve structures, which is ever-increasing with age, leads to a higher degree of conditioning and/or effectiveness. These reflexes become even more active when pathological conditions such as circulatory or respiratory distress demand constant vigilance. The increased tolerance to oxygen want in older persons is also confirmed by the reduced electrocardiographic changes to gradually increased oxygen want in the higher age groups of healthy persons (May, S. H.: Electrocardiographic Response to Gradually Induced Oxygen Deficiency: I. Response of Normal Hearts in Various Age Groups, *Am. Heart J.* **17**:667, 1939). Probably it may be precisely the decreased susceptibility to anoxia that largely contributes to the amazingly high survival rate of the aged in surgery.

PATIENTS WITH CANCER

To the Editor:—The article "What Philadelphia Physicians Tell Patients with Cancer," THE JOURNAL, Nov. 7, page 901, is very timely and well prepared. The last paragraph stating that studies are needed to determine which patients with cancer might benefit by being told that they have cancer leads me to believe that the authors are not totally in agreement with the view given by the majority of their medical associates in Philadelphia. I would like to refer to an article published in *The Journal of the Indiana State Medical Association*, April, 1953, entitled "Should Patients Be Told When the Diagnosis Is Cancer?"

I conducted a survey of patients (477) between the ages of 18 and 90 of this area to determine if patients desired to know whether or not they had cancer, whether they desired that their close relatives be told if they were afflicted with cancer, whether they actually thought persons with cancer could be fooled into thinking they did not have it, and who they thought should tell the patient about the diagnosis of cancer. I prepared a questionnaire with room on it for answers and reasons. In general, the greatest number of persons not only desired the truth but also desired that their close relatives be informed. A large majority did not feel that patients could be fooled. An overwhelming number thought the physician should be the one to tell the patient the facts about his illness. There were many extremely thought provoking comments by the patients; a few are included in the article. Many persons expressed the desire for cooperation between the physician, minister, and close relatives in handling the situation. There was no great difference of opinion among age groups and sex, but there was definite evidence that the age group 18 to 35 and that women more than men seemed to express greater trust and confidence in their physician. The age group 36 to 50 seemed more cancer conscious than other age groups. Answers did not seem to vary with occupations or religions however, persons of the business and professional groups gave more extensive reasons for their answer. Patients repeatedly expressed the desire for truth, conscientiousness, morality trustworthiness, and a Christian attitude on the part of th physician when handling cancer problems and all patient doctor relationships.

It is my firm opinion that the patient's desires should b followed in this matter rather than the physician's. There ar very few exceptions. Reasons for the patient's knowledge o his condition are given in the article mentioned, as well a the exceptions. I found that patients have reasons for wantin to know the truth about whether or not they have cancer fa more numerous and important than physicians ever dreame of. Patients have shown that they can take it better than th dreadful fear and indecision of whether their physician i trying to shield them from the fact that they actually hav cancer. Beside that, the type of treatment employed usuall is indicative to an intelligent patient that he probably ha cancer.

EXCHANGE TRANSFUSION IN HEMOLYTIC DISEASE OF THE NEWBORN

To the Editor:—Any case of erythroblastosis fetalis shoul be taken under care prenatally. Every pregnant woman shoul have her Rh blood type ascertained. If she is Rh negative an her husband is Rh positive, blood should be drawn in the thir month of pregnancy to test for the presence or absence o antibodies to the Rh factor and to be used as a basis fo comparison with subsequent samples. This should be don even in primiparas, because of the possibility of previou transfusion with Rh-positive blood, of its intramuscular injection, or of a previous undiagnosed incomplete pregnancy Other titers may be obtained according to individual discretion but at least one titer should be obtained in the seventh month of pregnancy for comparison. If there is a rise in titer, hemolytic disease should be anticipated. Generally speaking, thos women with the highest rise in titer will deliver the mos severely affected infants, but there are rare exceptions to thi rule.

If the rise in titer is late (32 weeks or later), the questio of induction of labor at 38 weeks arises; this is a controversia point, but should be considered especially if the rise is hig and precipitous, always remembering that prematurity carrie with it a higher incidence of kernicterus. A titer drawn fou to six weeks post partum may show a rise, even if no antibodies were noted during pregnancy. This should be note for future use. If there is a titer carryover from a previou pregnancy, with no rise in titer during the present pregnancy hemolytic disease should still be anticipated, although, if the husband is heterozygous for the Rh factor, the child may be Rh negative. Rh-negative blood that is compatible with the mother's serum should be available for transfusion, since it is her antibodies that are responsible for the red blood cell destruction in the child.

When a child of an Rh-negative mother is born, a hemoglobin specimen should be taken from the cord rather than from a capillary (this varies greatly with the time of tying of the cord). A Coombs' test should be done on heel or venous blood from the infant, as well as a complete blood cell count, reticulocyte count, and serum bilirubin determination. (Cord serum bilirubin levels are unreliable, since the bilirubin may escape into the maternal circulation.) In the presence of a positive reaction to a Coombs' test, which indicates that the maternal antibodies are attached to the infant's red blood cells, the indications for exchange transfusion are one or more of the following factors: (1) a cord hemoglobin of less than 14.5 gm. or a capillary hemoglobin of less than 15.5 gm. at birth; (2) previous history of erythroblastosis in a sibling; (3) prematurity; (4) reticulocytosis over 10%; (5) bilirubinemia over 20 mg. per 100 cc. in first 24 hours or an increase of serum bilirubin at a rate of 1 mg. per 100 cc. per hour; and (6) clinical picture of hepatomegaly, splenomegaly, jaundice, edema, petechiae, and pallor.

The most recent writings on this subject do not discuss the relative merits of multiple small transfusions and exchange transfusion. It has already been established to the satisfaction of Diamond, Levine, Mollison, Cutbush, and others that the clinical course of hemolytic disease of the newborn cannot be forecast and that the results are much better if exchange transfusion is done on all infants that require therapy. In experienced hands, this procedure is not unduly traumatic or of excessively long duration. Aftercare in these patients must be very close. Hemoglobin and serum bilirubin determinations must be repeated frequently (as indicated by results of previous determinations). If anemia recurs, a small transfusion is indicated. If the serum bilirubin level rises beyond 20 mg. per 100 cc., another exchange transfusion is indicated. This happens rarely, but the possibility must be considered.

CHLOROPHYLL AND DEODORIZATION

To the Editor:—An editorial entitled "Chlorophyll and Deodorization" in the Oct. 24 issue of The Journal quoted incorrectly from my paper presented before the American Dental Association annual meeting on Sept. 29, 1953. The correct quotation, with the word "protective" reinserted, was "Claims that toothpastes containing chlorophyll can give a protective deodorizing effect for several hours should be viewed with suspicion." The point I was trying to make, and which is missed in the misquotation, is that, since most of the toothpaste placed in the mouth on a toothbrush is quickly diluted by water and saliva, it is expecting a little too much that the amount remaining in the mouth after several hours will offer important protection against new odor agents placed in the mouth. While the deodorizing properties of chlorophyll derivatives have not been a major concern of my research with these materials since 1948, it has been my experience that the majority of samples of chlorophyll derivatives I have worked with will deodorize many substances, if brought in contact with them in sufficient concentration, either in vitro or in the oral cavity.

It is probably a form of justice that the overextravagant promotion of these materials has resulted in an almost fanatic skepticism toward any positive research findings concerning chlorophyll derivatives. Since two wrongs do not make a right, however, I felt it pertinent to point out the correction in respect to the quotation from my paper and my position in respect to deodorization as expressed in the paper.

John W. Hein, D.M.D., Ph.D.
University of Rochester
260 Crittenden Blvd.
Rochester 20, N. Y.

To the Editor:—I was interested in the editorial "Chlorophyll and Deodorization" in The Journal, Oct. 24, 1953, and the correspondence in the same issue. It is understandable that the wide claims for the deodorizing properties of the agent are being questioned. I think it would be a good idea to question some of the other claims that have been made for chlorophyll preparations, especially those relating to an alleged effect on wound healing. I am not familiar with a single clinical or experimental study that has proved conclusively that chlorophyll is beneficial. It is true that many wounds have healed under a chlorophyll ointment, but no untreated control wounds were provided. During World War II, a burn study unit at the Henry Ford Hospital undertook to evaluate chlorophyll, with wound healing experiments on guinea pigs and in clinical wounds of many types (Lam, C. R., and Brush, B. E.: Chlorophyll and Wound Healing: Experimental and Clinical Study, *Am. J. Surg.* 80:204, 1950). It was our conclusion that it could not be demonstrated that chlorophyll has a therapeutic effect.

PLASTIC REAGENT BOTTLES FOR ALKALIS

To the Editor:—Anyone who uses strong alkalis, such as sodium hydroxide solution—and this includes most practitioners and medical technicians—wishes at times to avoid somehow the etching properties of these reagents. Because of the etching properties, the inner surface of a glass bottle is dissolved and smudged. The reagent itself becomes a complex suspending a brackish waste that interferes with proper usage. I found it necessary to renew the sodium hydroxide solution in my laboratory every two weeks, and that became a nuisance. These strong alkali reagents are by far the most useful in the everyday hunt for fungi when examining and diagnosing cutaneous lesions and eruptions and excretions from the bronchial tree, lungs, and gastrointestinal tract. Numerous other tests and procedures in the medical and chemical laboratory depend on the availability of a supply of strong alkali solution.

Plastics today are commonplace and are fashioned into a thousand and one objects. They can substitute for practically any structural material. Plastic containers for cosmetics and commercial products fill the shelves of shops and possess very obvious advantages, such as light weight, lack of fragility and brittleness, and the capacity to change shape slightly and therefore to fit in spaces better than rigid glass. Beside, plastics are relatively inert and, unlike glass, do not react with strong alkali. Bottles made of these newer materials should be ideal for storing these reagents. In our laboratory, this was tested, and it was found that strong alkali, such as sodium or potassium hydroxide, solutions keep almost indefinitely without spoiling. Bottles for the purpose come in various styles, shapes, and sizes with short or drawn out necks that open into wide mouths or small tips to deposit even a drop or two. Strong alkali solutions slowly take up carbonic acid from the air and after a time lose part of their clarity; however, if the reagent bottle is kept well stoppered between use, the content remains clear and fresh for years.

RUPTURE OF AORTIC ANEURYSM INTO ESOPHAGUS

To the Editor:—I have read with interest the article by Drs. Calenda and Uricchio on "Gastrointestinal Hemorrhage Due to Rupture of Aortic Aneurysm into the Esophagus" (*J. A. M. A.* **153**:548-549 [Oct. 10] 1953). These authors correctly emphasize the advisability of considering rupture of an aortic aneurysm in the differential diagnosis of hematemesis and melena. I doubt, however, that rupture of an aortic aneurysm into the esophagus is as rare as they have stated. Certainly more than five cases have been described in the world literature in the past 27 years. Baer and Loewenberg have reported cases of aortic aneurysm rupturing into the esophagus or duodenum (Loewenberg, S. A., and Baer, S.: *Am. Heart J.* **32**:653 [Nov.] 1946; Baer, S., and Loewenberg, S. A.: *Gastroenterology* **10**:617 [April] 1948). In addition, Dr. Harold L. Goldburgh and I discussed the gastrointestinal complications of dissecting aneurysm at some length (Baer, S., and Goldburgh, H. L.: *Am. Heart J.* **35**:198 [Feb.] 1948). Included in this report of 44 cases of dissecting aneurysm are at least 2 cases in which there was rupture of the aneurysm into the esophagus. I believe that a more detailed search of the literature will reveal several other cases in which an aortic aneurysm perforated into the gastrointestinal tract.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

ADDITIONAL HOSPITALS REGISTERED

The following hospitals were registered by the Council on Medical Education and Hospitals of the American Medical Association at its meeting in St. Louis, Nov. 30, 1953:

Ellis-Meyer Hospital Clinic, Decatur, Ala.
El Reposo Sanitarium, Florence, Ala.
Fitts-Hill Hospital, Montgomery, Ala.
Randolph County Hospital, Roanoke, Ala.
Mesa Sanitarium, Mesa, Ariz.
Crippled Children's Hospital, Phoenix, Ariz.
Mercy Hospital-Gozzolu Memorial, Brinkley, Ark.
Des Arc General Hospital, Des Arc, Ark.
Baxter County Community Hospital, Gassville, Ark.
Izard County Memorial Hospital, Melbourne, Ark.
Saltzman Hospital, Mountain Home, Ark.
Crawford County Memorial Hospital, Van Buren, Ark.
Cross County Hospital, Wynne, Ark.
Healdsburg General Hospital, Healdsburg, Calif.
Shriners Hospital for Crippled Children, Los Angeles
Westmoreland Sanitarium, Los Angeles
North Hollywood Maternity Hospital, North Hollywood, Calif.
Salinas Valley Memorial Hospital, Salinas, Calif.
California State Polytechnic College Hospital, San Luis Obispo, Calif.
Kit Carson County Memorial Hospital, Burlington, Colo.
Montrose Memorial Hospital, Montrose, Colo.
Simla Community Hospital, Simla, Colo.
Cove Hill Manor, Uncasville, Conn.
Hadley Memorial Hospital, Washington, D. C.
Arcadia General Hospital, Arcadia, Fla.
Manatee Veterans Memorial Hospital, Bradenton, Fla.
Memorial Hospital, Hollywood, Fla.
Grant Haven Convalescent Home, Jacksonville, Fla.
Galey Memorial Hospital, Key West, Fla.
North Shore Hospital, Miami, Fla.
Arlington City Hospital, Arlington, Ga.
Emanuel County Hospital, Swainsboro, Ga.
Carmi Township Hospital, Carmi, Ill.
Memorial Hospital, Carthage, Ill.
Belmont Rest Home, Chicago
Louis A. Weiss Memorial Hospital, Chicago
Mark Howard Home, Chicago
Ogden Park Convalescent Home, Chicago
Veterans Admin. Hospital, Chicago
Wrightwood Home, Chicago
Student Health Service, Northwestern University, Evanston, Ill.
New Glenview Convalescent Home, Glenview, Ill.
Condell Memorial Hospital, Libertyville, Ill.
Marion Memorial Hospital, Marion, Ill.
Whitley County Memorial Hospital, Columbia City, Ind.
Veterans Admin. Hospital, Indianapolis
Clarke County Hospital, Osceola, Iowa
Sioux Center Community Hosp. and Health Center, Sioux Center, Iowa
Lutheran Hospital, Sioux City, Iowa
Community Memorial Hospital, Sumner, Iowa
Hanover Hospital, Hanover, Kan.
Stevens County Hospital, Hugoton, Kan.
Wichita County Hospital, Leoti, Kan.
Cheyenne County Hospital, St. Francis, Kan.
Washington County Hospital, Washington, Kan.
Knox Hospital, Barbourville, Ky.
Clinton and Hickman County Hospital, Clinton, Ky.
New Castle Sanitarium, New Castle, Ky.
Methodist Hospital, Pikeville, Ky.
Henry Cook Pope Hospital, Richmond, Ky.
Clark County Hospital, Winchester, Ky.
Franklin Foundation Hospital, Franklin, La.
Jennings American Legion Hospital, Jennings, La.
Otis General Hospital, Cambridge, Mass.
Springfield Hospital, Springfield, Mass.
Memorial Hospital, Onekama, Mich.
Trenton Medical Hospital, Trenton, Mich.
Sandstone State Hospital, Sandstone, Minn.
Zumbrota Community Hospital, Zumbrota, Minn.
Cosby Hospital-Clinic, Iuka, Miss.
Watkins Memorial Hospital, Quitman, Miss.
Stone County Hospital, Wiggins, Miss.
Sheridan Memorial Hospital, Plentywood, Mont.
Cottage Hospital, Woodsville, N. H.
Hunterdon Medical Center, Flemington, N. J.
Franklin Hospital, Franklin, N. J.
Passaic County Welfare Home, Paterson, N. J.
New Jersey Neuro-Psychiatric Institute, Skillman, N. J.
Meadows Home for the Aged and Chronically Ill, Las Vegas, N. Mex.
Swedish Hospital, Brooklyn
Chronic Diseases Research Institute, Buffalo
Veterans Admin. Hospital, Syracuse, N. Y.
Angel Hospital, Franklin, N. C.
Shaw Memorial Hospital, Oxford, N. C.
Towner County Memorial Hospital, Cando, N. Dak.
Wood County Hospital, Bowling Green, Ohio
Fostoria City Hospital, Fostoria, Ohio
Edmond Hospital, Edmond, Okla.
Moton Memorial Hospital, Tulsa, Okla.
Pacific Communities Hospital, Newport, Ore.
Kalkhof Hospital and Clinic, Erie, Pa.
Valley Forge Heart Institute and Hospital, Fairview Village, Pa.
Wolffe Clinic and Hospital, Philadelphia
Dell Rapids Hospital, Dell Rapids, S. Dak.
Bristol Memorial Hospital, Bristol, Tenn.
Dan German Hospital, Franklin, Tenn.
Laughlin Clinic-Hospital, Greeneville, Tenn.
Kenneth Brown Hospital, Lewisburg, Tenn.
Henry County General Hospital, Paris, Tenn.
Matagorda General Hospital, Bay City, Texas
Bronte Hospital, Bronte, Texas
Hammond Memorial Hospital, Bryan, Texas
Driscoll Foundation Children's Hospital, Corpus Christi, Texas
Navarro Clinic-Hospital, Corsicana, Texas
Dublin Hospital, Dublin, Texas
Eastland Memorial Hospital, Eastland, Texas
Eldorado Clinic Hospital, Eldorado, Texas
Oak Lawn Hospital, Gilmer, Texas
Hamilton Clinic and Hospital, Hamilton, Texas
U. S. Air Force Hospital, Houston, Texas
Jenkins Clinic-Hospital, Hughes Springs, Texas
Jacksboro Hospital, Jacksboro, Texas
Hardin County Hospital, Kountze, Texas
Bucy-Glenn Clinic Hospital, Linden, Texas
Medical-Surgical Hospital, Lockney, Texas
Goodnight Hospital, Lubbock, Texas
Crockett County Hospital, Ozona, Texas
Rankin Hospital, Rankin, Texas
Gaines Clinic-Hospital, Seminole, Texas
Briscoe County Hospital, Silverton, Texas
Sinton Hospital, Sinton, Texas
Tomball Hospital, Tomball, Texas
Willapa Harbor Hospital, South Bend, Wash.
Washington State Penitentiary Hospital, Walla Walla, Wash.
St. Luke's Hospital, Bluefield, W. Va.
Staats Hospital, Charleston, W. Va.
Grant Community Hospital, Lancaster, Wis.
Attic Angel Nursing Home, Madison, Wis.
Wisconsin Neurological Hospital, Madison, Wis.
War Memorial Hospital, Powell, Wyo.
Memorial Hospital of Carbon County, Rawlins, Wyo.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Scientific Tests: Conclusiveness of Paternity Test.—This was a bastardy proceeding. From judgments for the defendant, the plaintiff appealed to the Essex county court, law division, New Jersey.

The question to be decided by this appeal, said the court, is: In a bastardy proceeding, where the only issue is the paternity of the illegitimate child, is the result of a blood grouping test disproving paternity to be treated as a form of expert evidence not necessarily barring a finding of paternity contrary to the test result, or is it to be considered conclusive evidence of non-paternity?

In seeking the answer to this question, said the court, it is not necessary to be concerned with how such evidence should be considered in a criminal or quasi-criminal proceeding where the blood is obtained without consent or if, as has been suggested, the results of blood grouping tests should be treated differently in those types of proceedings than in civil proceedings. Although certain formal aspects of a bastardy proceeding resemble a criminal rather than a civil proceeding, and although dictum will be found from time to time to the effect that it is of a quasi-criminal nature, it appears settled in this State, as well as in a majority of our sister states, that a bastardy case is a civil proceeding. Furthermore, the parties here consented to the test. In fact, said the court, the test by Dr. Lester Unger was conducted pursuant to an order obtained by the plaintiff while the appeal was pending. The importance of determining the legal effect of a test result of non-paternity is brought into sharp focus by the record in this case. At the first trial in the court below a jury verdict in favor of the plaintiff was set aside by the trial judge. At the second trial, also before a jury, the magistrate directed a verdict in favor of the defendant on the basis of the result of the test performed by Dr. Philip Levine. In this court, although available, a jury trial was not demanded. While the case was pending on appeal here and before trial, the plaintiff applied for an order to have a blood grouping test conducted by Dr. Lester Unger, an expert of her own choosing. Being satisfied as to Dr. Unger's qualifications, an appropriate order was entered by this court, and his report setting forth his findings that defendant could not be the father of the child was admitted in evidence at the subsequent trial. Dr. Levine, one of the world's outstanding authorities in this field, testified at the trial in this court that the test conducted by him conclusively showed that defendant could not be the father of the child. Dr. Levine further testified that Dr. Unger is recognized as an outstanding serologist and fully competent to perform blood grouping tests. No suggestion is made that these tests were not properly conducted, and the record conclusively demonstrates that they were performed in accordance with the highest standards of accepted practice. Excluding the results of the blood grouping tests, the other evidence in the case preponderates in favor of the plaintiff, and, without these test results, the judgment of non-paternity entered in the court below would have to be set aside and a judgment entered here that the defendant is the father of the child born to the plaintiff.

It is universally accepted in medical and scientific fields, said the court, that the result of a blood grouping test disproving paternity or, to use the language of the statute, indicating definite exclusion of parentage, is not an expression of opinion upon which experts can differ but, rather, is the statement of a scientifically established fact. It is a scientifically established fact just as it is a scientifically established fact that the world is round. As such it should be accepted by the courts of law. For a court to declare that these tests are not conclusive would be as unrealistic as it would be for a court to declare that the world is flat. This a court of law whose prime function is to ascertain truth and administer justice should not do. Accordingly, it is held that the results of the blood grouping tests conclusively establish that the defendant is not the father of the illegitimate child born to the plaintiff.

The judgment in favor of the defendant was affirmed. *Ross v. Marx, 90 A. (2d) 545 (New Jersey 1952).*

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—Ed.

TO HELP THE PATIENT PAY

When a man wants to buy an expensive item such as a television set and he does not have ready cash, he often arranges to pay for the set on a weekly or monthly installment plan. Installment buying has become so much a part of the American economic system that there is no reason why medical care cannot be purchased in the same way. Although it is not being too mercenary to help a patient budget for his medical care if the physician's attitude toward the system is right, the suggestion must be implanted tactfully. Unless patients are undergoing extensive treatment, it is generally wise to encourage them to pay for routine visits before they leave the office. Most people come prepared to pay for the call but leave without paying because they hesitate to bring up the subject themselves. The doctor can smooth the way to payment and relieve patients' uncertainty by saying at the end of the visit: "My usual charge for an office call is ———. If you would like to pay today, please stop at my secretary's desk as you leave." Or, if the patient stops at the secretary's desk to make another appointment, the secretary can say: "Would you like to pay for your visit today?" as she reaches for her receipt book. Encouraging pay-as-you-go plans eases the strain on the patient's pocketbook and cuts billing and collecting procedures in the doctor's office.

Patients who cannot pay for their medical care immediately should be given an opportunity to arrange payment plans to suit their needs. Payment plans that allow the patient to pay a certain amount over a period of time make it easier for him to meet the unexpected cost of illness. It is not necessary to use such commercial terms as "installment buying" or "time-payment plans." When a patient is upset at the prospect of paying your fee, it may be suggested: "Mrs. Smith, if you think you will have difficulty paying for your treatments at one time, we can work out some special arrangements." The patient probably will ask what you have in mind, and the discussion very naturally eases into types of payment plans. Payment plans can be handled in the office by the physician and his secretary. For example, in fixed fee cases such as immunizations and periodic check-ups of infants, it is easy to work out an installment plan by dividing the total sum by the probable number of calls or number of months during which care will be provided and asking the patient to pay a portion of the sum at monthly intervals or at each visit. Suppose a patient comes to the office during the third month of pregnancy. She can work out a seven-month payment plan with the doctor and make her last payment correspond with her last postnatal visit.

When the time element is not definite, a 10 month or 12 month period is usually agreeable to both patient and physician for budgeting medical care. The physician must carefully explain just what medical services are being provided for the monthly sum, however, so that should an emergency arise that requires additional treatment during this period, the patient is not angry when he finds he must pay a larger sum than that agreed on. Sometimes a physician can offer an installment plan to patients who are several months behind in their payments. A doctor might send a little card with a message reading something like this: "Instead of mailing you your statement, I am sending you this card so you can remit small monthly payments to clear up your account. Just return your check or a cash amount with this card, and we will receipt it and return it so you can use it again next month." This informal approach is much less frightening than a formal promissory agreement, and the patient usually is relieved that his medical bills can be settled so easily.

Banks, reputable loan companies, and other organizations sometimes offer plans for financing medical bills. Medical societies, too, in some areas have set up medical credit bureaus to help patients meet their medical obligations. These organizations usually pay the doctor in full for his services and lend the money to patients at a small rate of interest. Physicians often deduct the interest charges from their fees. The doctor may suggest to his patient that such plans are available and perhaps give a card of introduction to the bank or bureau if the patient is interested. There are certain dangers in outside financing of medical bills—unscrupulous organizations could press patients for payments in an unethical way, creating bad feeling. The physician should carefully investigate any such available plans and determine if their use is justified. However, ethical plans can be a real service to patients who honestly want to pay their medical bills.

MEDICAL MOTION PICTURES

The Warning Shadow: 16 mm., color, sound, showing time 16 minutes. Produced in 1953 by Herbert Kerkow for the American Cancer Society and the National Cancer Institute. Procurable on loan from the American Cancer Society, 47 Beaver Street, New York 4.

This is a fine picture of a dramatic subject. The opening portion, dealing with the first successful pneumonectomy on a patient (who happened to be a doctor), has simplicity and a sincerity that carries conviction. The average layman, to whom this picture is directed, will be much impressed by the fact that a physician had the same problem as the layman when considering an operation of such severity. The fact that neither the patient nor the surgeon discussed in the picture are actors adds an authenticity to the story that cannot be secured by statistics or scientific detail. Later on, a group of successfully treated lung cancer patients are shown. These persons, who are now apparently healthy, may be the means of saving the lives of thousands of others. It is not a technical picture and should not be considered as such. The information presented is sufficient to stimulate interest and action on the part of a possible patient and, most important, refer him to his doctor for information and diagnosis. This picture is heartily recommended for lay groups of either men or women. The photography and narration are excellent.

MEDICAL LITERATURE ABSTRACTS

UNITED STATES

A.M.A. Am. J. Diseases Children, Chicago

86:395-552 (Oct.) 1953

*Reactions Following Antirabies Prophylaxis. N. H. Blatt and M. H. Lepper.—p. 395.

*Electrophoretic Analyses of Plasma or Serum Proteins of Rheumatic Fever Patients in Relation to Stages of Disease. R. L. Jackson, H. G. Kelly, E. K. Smith, P. Wang and J. I. Routh.—p. 403.

New Treatment for Atelectasis of Newborn. W. G. Love Jr. and B. Tillery.—p. 423.

Growth and Metabolism in Normal and Thyroid-Ablated Infant Rhesus Monkeys (Macaca Mulatta). L. B. Lusted, D. E. Pickering, D. Fisher and F. S. Smyth.—p. 426.

Completely Automatic Miller Aerosol Device. C. M. Trossman.—p. 436.

Reactions Following Antirabies Prophylaxis.—Reactions to rabies vaccine developed in 16 patients, all but one of whom came from a group of 2,193 persons who received antirabies inoculations from the Chicago Health Department in 1950, 1951, and the first three months of 1952. Eight patients had reactions without evidence of central nervous system involvement, and eight had reactions with such signs. One of this second group died, and three had residual neurological symptoms after treatment. The signs and symptoms of antirabies vaccine reaction indicating that therapy should be discontinued are principally occurrence of an otherwise unexplained fever, paresis, radicular pain, and headache. Any otherwise unexplainable complaint must be regarded as suspicious. An intradermal skin test using antirabies vaccine diluted to 1:10 was found to be positive in all patients in whom a clinical reaction to rabies vaccine developed; but it was positive in 60% of all patients being vaccinated. Persons who have not been inoculated with rabies vaccine have negative skin tests. Corticotropin was given to three of the patients with the most serious involvements. Two responded well, and the third, who received the drug late in the course of the disease, had only questionable benefit. It was suggested but not proved that corticotropin may have been effective in treating these patients.

Plasma or Serum Proteins in Patients with Rheumatic Fever.—A detailed study of the plasma or serum proteins of 77 children with definite rheumatic fever and five patients with chorea without other manifestations of rheumatic fever is reported. The total proteins and percentage composition of albumin, alpha$_1$ globulin, alpha$_2$ globulin, beta globulin, fibrinogen, gamma' globulin, and gamma globulin of the blood are given for patients in the following stages of the disease: (1) early acute without decompensation, (2) late acute without decompensation, (3) early, middle, and late subacute without decompensation or recent infection or exacerbation, (4) inactive without recent infection or exacerbation, (5) acute with decompensation, (6) early, middle, and late subacute without decompensation but with recent mild intercurrent infection or exacerbation, (7) active chorea only, and (8) remittent type in various stages. The changes in the serum protein components of the blood that take place along with the antibody response when a child's system adjusts to acute disease were found to have a definite pattern, as evidenced by the 205 plasma or serum specimens analyzed in the course of this study. The percentage composition of albumin, fibrinoge and the globulins alpha$_1$, alpha$_2$, gamma', and gamma markedly altered in the acute stage of the disease. The retur to normal mean values as the disease regresses is gradual f albumin, fibrinogen, and alpha$_2$ and gamma globulins; alph and gamma' globulins are elevated generally only in the acu stage. Changes in the percentage composition of beta globul are not correlated with the stages of the disease; the mea values for total proteins are slightly elevated for all subgrou of uncomplicated rheumatic fever and significantly elevated the late subacute stage. The mean values of serum prote fractions for the group of patients with inactive rheumat fever indicate that the patients as a group are capable normal protein metabolism.

A.M.A. Arch. Ophthalmology, Chicago

Echinococcus Cyst of Eyeball. O. Litricin.—p. 506.

Endogenous Uveitis in Children.—The occurrence of acti endogenous uveitis was observed in five girls and seven bo between the ages of 5 and 15 years. The disease was diagnos as chorioretinitis without anterior segment involvement in of the 12 patients, while it was described as iritis or irid cyclitis, with or without posterior involvement, in the r maining 10. Of the 10 patients, 4 had definite concurre rheumatoid arthritis and 2 had a history of "arthritis" witho any residual joint deformity. No other causative factor w noted in any of these patients, except for sarcoidosis in on The cause was undetermined in the remaining four patient The anterior uveitis was of granulomatous type in two patient nongranulomatous in three, and of quiet serous type in fiv This last type was noted in most of the cases of iritis ass ciated with juvenile rheumatoid arthritis collected from t literature. Of the author's five patients with this last ty of anterior uveitis, three had definite rheumatoid arthrit one had a history of arthritis, and in one the cause was u determined. Two of the 10 patients with anterior uveit associated with typical rheumatoid arthritic deformities of th proximal interphalangeal joints bilaterally and sarcoid lesio on the extensor surfaces of both arms in one, and with synovi thickening of the enlarged right knee joint in the other, a described in detail. A brief review of the literature on th triad of band-shaped keratopathy, iritis, and juvenile rhe matoid arthritis is presented, and the association of rhe matoid arthritis with juvenile uveitis is stressed.

Hyperophthalmopathic Graves' Disease.—The clinical pictur of 19 patients with hyperophthalmopathic Graves' diseas reported on by Hedges and Rose was dominated by sever or progressive ocular signs. Proptosis was symmetrical in 1 patients and asymmetrical in 9 at the onset of exophthalmos Congestive signs were present without corneal damage i

---

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

seven patients and with corneal damage in four. Eight patients showed no congestive signs at any time. Limitation of ocular movement was noted at the time of first examination in 11 patients. Seven patients suffered some loss of visual acuity, but eventual recovery of vision was notable in all. Two of these patients showed central visual field defects indicative of optic nerve fiber bundle damage. Exophthalmos attained its maximum in from 4 to 12 months in 16 of the 19 patients. Recession, varying from 3 to 7 mm., occurred in from 1 to 6 years in 8 patients, while no significant recession from maximum levels occurred during 2 to 12 years in 11 patients. When progressive, hyperophthalmopathic syndrome generally tended to become stabilized in from 4 to 12 months after which the inflammatory, congestive, and sympathicotonic manifestations tended to regress and the proptosis either remained stationary or gradually receded. Of the 19 patients, 14 manifested initially some degree of thyrotoxicosis; of 4 euthyroid patients, 2 may have been previously thyrotoxic; and 1 patient remained hypothyroid throughout. Seven of the 19 patients received thiouracil compounds and stable iodine over long periods. When the metabolic rate returned to normal, there was no increase in ophthalmopathy. Partial thyroidectomy was done in the presence of exophthalmos in four patients with no subsequent exacerbation of the ophthalmopathy. Treatment of thyrotoxicosis in 11 patients caused no significant exacerbation of the ocular syndrome. Nine of the 19 patients received desiccated thyroid and diethylstilbestrol over long periods. No correlation between this treatment and the course of the ophthalmopathy was observed. Eighteen patients received irradiation treatment to the pituitary; a significant recession in exophthalmos occurred in only two patients. Seven patients showed gradual decrease in congestive ocular signs within four to six months. In five of these patients treatment was given after the ophthalmopathy had been present for six to eight months. It is possible that a spontaneous regression in congestive signs could explain this apparent improvement. The authors' observations failed to indicate a relationship between the onset and course of the ophthalmopathic phenomena and those of associated thyroid dysfunction. The concept that exophthalmos is divided into the thyrotropic and the thyrotoxic form is not tenable. The possible role of orbital tissue hypersensitivity in the pathogenesis of hyperophthalmopathic phenomena of Graves' disease is suggested. Evaluation of therapy in patients with hyperophthalmopathic Graves' disease is hampered by the tendency toward spontaneous remissions and exacerbations and by the lack of control studies. The use of stable iodine and desiccated thyroid and, in selected progressive cases, pituitary irradiation seems to be safe therapeutic policy. Local measures may be employed when indicated. Surgical decompression of the orbit is a measure of last resort.

American Journal of Surgery, New York

Spontaneous Involution of Cutaneous Vascular Tumors.—For the last five years 59 private patients with vascular tumors (almost all having strawberry and cavernous hemangiomas) have been left untreated by Ronchese. Letters sent to the patients to learn about the results were answered by 33; 24 of these stated that the birthmark had disappeared completely or that the remnants were cosmetically satisfactory; 4 said that the birthmark did not change, and 5 were treated by surgery or irradiation. The occurrence of spontaneous involution of a cutaneous vascular tumor is described in three patients. A doughy, doughnut-shaped, flesh-colored tumor below the knee of the first patient, a baby boy two weeks old, vanished in six months leaving only a slightly wrinkled surface. "Spontaneously developing and spontaneously involuting telangiectasis" appeared several times in the same area of the left cheek of the second patient, a man aged 75, and lasted only a few days. This occurred several times over a period of months and was symptomless. There was no clue as to the cause. The third patient was a baby girl 16 days old with a rubbery, blue-green patch on her right lower abdominal quadrant. Because of its consistency, it suggested fat necrosis of the newborn and hemangioma. It involuted after six months. It is difficult to determine the exact percentage of spontaneous involution of cutaneous vascular tumors because of the prevailing opinion, especially among radiologists and surgeons, that it is unwise or dangerous to leave hemangiomas untreated. There is also parental unwillingness to wait for three or four years for spontaneous involution. Consequently the great majority of such patients receive treatment in one form or another. The author does not advocate expectant therapy for all cases; however, being convinced that a large majority do involute spontaneously, he is in favor of no therapy in selected cases in which the lesions are located in covered body areas or may be easily removed surgically at a later date in the event spontaneous involution does not occur. Treatment usually is indicated in exposed parts if the hemangioma is small because there are easy, quick, and safe methods, or if it is large because it may be "the exceptional one" that will not vanish and later therapy will be more difficult. Expectant therapy has its place with the use of radium and should be given due consideration.

Clinical Evaluation of Isoniazid.—Isoniazid alone was given a therapeutic trial in 61 tuberculous patients with active and potentially reversible exudative, caseating, or cavernous lesions. After a preliminary control period of three weeks of bed rest without drug therapy, isoniazid was given to each patient in daily doses of 3 to 4 mg. per kilogram of body weight, divided into three doses. If there was a substantial gain in weight, the dose of isoniazid was usually increased. It was planned to treat each patient with isoniazid alone for a minimum of three months after the control period of bed rest. In some patients, the lack of improvement or even the progression of the disease made it unwise to follow this plan rigidly. Isoniazid was discontinued, and streptomycin and *p*-aminosalicylic acid were substituted. Direct comparison of these drugs was thus afforded in these patients. Results showed that isoniazid is probably less effective than streptomycin in patients with caseocavernous pulmonary or extrapulmonary tuberculosis, while isoniazid is probably superior to streptomycin in those with tuberculous meningitis. This superiority in meningitis may be due to the potent intracellular activity of isoniazid, as well as to its superior diffusibility into the meninges. The therapeutic response of basal pulmonary tuberculosis to isoniazid is less dependable and more variable than to streptomycin and *p*-aminosalicylic acid. Favorable changes

Reactions Following Antirabies Prophylaxis.—Reactions to rabies vaccine developed in 16 patients, all but one of whom came from a group of 2,193 persons who received antirabies inoculations from the Chicago Health Department in 1950, 1951, and the first three months of 1952. Eight patients had reactions without evidence of central nervous system involvement, and eight had reactions with such signs. One of this second group died, and three had residual neurological symptoms after treatment. The signs and symptoms of antirabies vaccine reaction indicating that therapy should be discontinued are principally occurrence of an otherwise unexplained fever, paresis, radicular pain, and headache. Any otherwise unexplainable complaint must be regarded as suspicious. An intradermal skin test using antirabies vaccine diluted to 1:10 was found to be positive in all patients in whom a clinical reaction to rabies vaccine developed; but it was positive in 60% of all patients being vaccinated. Persons who have not been inoculated with rabies vaccine have negative skin tests. Corticotropin was given to three of the patients with the most serious involvements. Two responded well, and the third, who received the drug late in the course of the disease, had only questionable benefit. It was suggested but not proved that corticotropin may have been effective in treating these patients.

Plasma or Serum Proteins in Patients with Rheumatic Fever.—A detailed study of the plasma or serum proteins of 77 children with definite rheumatic fever and five patients with chorea without other manifestations of rheumatic fever is reported. The total proteins and percentage composition of albumin, $alpha_1$ globulin, $alpha_2$ globulin, beta globulin, fibrinogen, gamma' globulin, and gamma globulin of the blood are given for patients in the following stages of the disease: (1) early acute without decompensation, (2) late acute without decompensation, (3) early, middle, and late subacute without decompensation or recent infection or exacerbation, (4) inactive without recent infection or exacerbation, (5) acute with decompensation, (6) early, middle, and late subacute without decompensation but with recent mild intercurrent infection or exacerbation, (7) active chorea only, and (8) remittent type in various stages. The changes in the serum protein components of the blood that take place along with the antibody response when a child's system adjusts to acute disease were found to have a definite pattern, as evidenced by the 205 plasma or serum specimens analyzed in the course of this study. The percentage composition of albumin, fibrinogen, and the globulins $alpha_1$, $alpha_2$, gamma', and gamma is markedly altered in the acute stage of the disease. The return to normal mean values as the disease regresses is gradual for albumin, fibrinogen, and $alpha_2$ and gamma globulins; $alpha_1$ and gamma' globulins are elevated generally only in the acute stage. Changes in the percentage composition of beta globulin are not correlated with the stages of the disease; the mean values for total proteins are slightly elevated for all subgroups of uncomplicated rheumatic fever and significantly elevated in the late subacute stage. The mean values of serum protein fractions for the group of patients with inactive rheumatic fever indicate that the patients as a group are capable of normal protein metabolism.

Endogenous Uveitis in Children.—The occurrence of activ endogenous uveitis was observed in five girls and seven boy between the ages of 5 and 15 years. The disease was diagnose as chorioretinitis without anterior segment involvement in of the 12 patients, while it was described as iritis or irido cyclitis, with or without posterior involvement, in the re maining 10. Of the 10 patients, 4 had definite concurren rheumatoid arthritis and 2 had a history of "arthritis" withou any residual joint deformity. No other causative factor wa noted in any of these patients, except for sarcoidosis in one The cause was undetermined in the remaining four patient The anterior uveitis was of granulomatous type in two patient nongranulomatous in three, and of quiet serous type in five This last type was noted in most of the cases of iritis asso ciated with juvenile rheumatoid arthritis collected from th literature. Of the author's five patients with this last typ of anterior uveitis, three had definite rheumatoid arthriti one had a history of arthritis, and in one the cause was un determined. Two of the 10 patients with anterior uveiti associated with typical rheumatoid arthritic deformities of th proximal interphalangeal joints bilaterally and sarcoid lesion on the extensor surfaces of both arms in one, and with synovia thickening of the enlarged right knee joint in the other, ar described in detail. A brief review of the literature on th triad of band-shaped keratopathy, iritis, and juvenile rheu matoid arthritis is presented, and the association of rheu matoid arthritis with juvenile uveitis is stressed.

Hyperophthalmopathic Graves' Disease.—The clinical pictur of 19 patients with hyperophthalmopathic Graves' diseas reported on by Hedges and Rose was dominated by sever or progressive ocular signs. Proptosis was symmetrical in 1 patients and asymmetrical in 9 at the onset of exophthalmos Congestive signs were present without corneal damage in

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

seven patients and with corneal damage in four. Eight patients showed no congestive signs at any time. Limitation of ocular movement was noted at the time of first examination in 11 patients. Seven patients suffered some loss of visual acuity, but eventual recovery of vision was notable in all. Two of these patients showed central visual field defects indicative of optic nerve fiber bundle damage. Exophthalmos attained its maximum in from 4 to 12 months in 16 of the 19 patients. Recession, varying from 3 to 7 mm., occurred in from 1 to 6 years in 8 patients, while no significant recession from maximum levels occurred during 2 to 12 years in 11 patients. When progressive, hyperophthalmopathic syndrome generally tended to become stabilized in from 4 to 12 months after which the inflammatory, congestive, and sympathicotonic manifestations tended to regress and the proptosis either remained stationary or gradually receded. Of the 19 patients, 14 manifested initially some degree of thyrotoxicosis; of 4 euthyroid patients, 2 may have been previously thyrotoxic; and 1 patient remained hypothyroid throughout. Seven of the 19 patients received thiouracil compounds and stable iodine over long periods. When the metabolic rate returned to normal, there was no increase in ophthalmopathy. Partial thyroidectomy was done in the presence of exophthalmos in four patients with no subsequent exacerbation of the ophthalmopathy. Treatment of thyrotoxicosis in 11 patients caused no significant exacerbation of the ocular syndrome. Nine of the 19 patients received desiccated thyroid and diethylstilbestrol over long periods. No correlation between this treatment and the course of the ophthalmopathy was observed. Eighteen patients received irradiation treatment to the pituitary; a significant recession in exophthalmos occurred in only two patients. Seven patients showed gradual decrease in congestive ocular signs within four to six months. In five of these patients treatment was given after the ophthalmopathy had been present for six to eight months. It is possible that a spontaneous regression in congestive signs could explain this apparent improvement. The authors' observations failed to indicate a relationship between the onset and course of the ophthalmopathic phenomena and those of associated thyroid dysfunction. The concept that exophthalmos is divided into the thyrotropic and the thyrotoxic form is not tenable. The possible role of orbital tissue hypersensitivity in the pathogenesis of hyperophthalmopathic phenomena of Graves' disease is suggested. Evaluation of therapy in patients with hyperophthalmopathic Graves' disease is hampered by the tendency toward spontaneous remissions and exacerbations and by the lack of control studies. The use of stable iodine and desiccated thyroid and, in selected progressive cases, pituitary irradiation seems to be safe therapeutic policy. Local measures may be employed when indicated. Surgical decompression of the orbit is a measure of last resort.

Clinical Evaluation of Isoniazid.—Isoniazid alone was given a therapeutic trial in 61 tuberculous patients with active and potentially reversible exudative, caseating, or cavernous lesions. After a preliminary control period of three weeks of bed rest without drug therapy, isoniazid was given to each patient in daily doses of 3 to 4 mg. per kilogram of body weight, divided into three doses. If there was a substantial gain in weight, the dose of isoniazid was usually increased. It was planned to treat each patient with isoniazid alone for a minimum of three months after the control period of bed rest. In some patients, the lack of improvement or even the progression of the disease made it unwise to follow this plan rigidly. Isoniazid was discontinued, and streptomycin and *p*-aminosalicylic acid were substituted. Direct comparison of these drugs was thus afforded in these patients. Results showed that isoniazid is probably less effective than streptomycin in patients with caseocavernous pulmonary or extrapulmonary tuberculosis, while isoniazid is probably superior to streptomycin in those with tuberculous meningitis. This superiority in meningitis may be due to the potent intracellular activity of isoniazid, as well as to its superior diffusibility into the meninges. The therapeutic response of basal pulmonary tuberculosis to isoniazid is less dependable and more variable than to streptomycin and *p*-aminosalicylic acid. Favorable changes in the chest roentgenogram were obtained in 43 (70%) of the 61 patients, while unfavorable radiographic changes were observed in the remaining 18 patients (30%). In 30 patients who were febrile during the preliminary control period, 14 remained febrile under isoniazid therapy, 7 became afebrile within one month of treatment, 6 within two months, and 3 within three months. Fifty patients gained a total of 577 lb. (261.7 kg.) during three months, for an average gain of 11.54 lb. (5.23 kg.). The extremes were a gain of 37 lb. (16.8 kg.) and a loss of 16 lb. (7.3 kg.). Many patients gained weight during the preliminary control period at a rate equal to or greater than the gain while under treatment with isoniazid. Clinical evidence was obtained of a "dissociation" of the therapeutic effect of isoniazid that consisted of simultaneous resolution of one lesion with progression of another in the same patient. It is suggested that many patients are infected with multiple strains of Mycobacterium tuberculosis some of which are resistant to isoniazid and others sensitive. The interaction of anatomic factors, such as the opening or closing of a bronchiole or the alteration of lymph flow by inflammation or fibrosis of a draining lymph node, and immunologic factors in different organs, with the seeding by chance of these organs with different ratios of resistant to sensitive strains of bacteria, is sufficient to explain the variations of response to isoniazid observed in the authors' patients. Visualization of the tuberculous infection as consisting of the action of antibiotics upon a heterogeneous population of numerous organisms with all degrees of sensitivity to streptomycin, isoniazid and *p*-aminosalicylic acid, strongly support the simultaneous use of these three drugs.

Pulmonary Resection for Tuberculous Disease.—Pulmonary resection for localized necrotic tuberculous lesions of the lung were performed on 221 patients who were followed one to five years postoperatively. The lesions involved only one lobe and were limited to an area not exceeding the extent of a minimal lesion as defined by National Tuberculosis Association standards. Of the 221 patients, 69 had cavitary lesions, 2 diffuse caseopneumonic, 96 caseonodose, and 54 tuberculoma. Excision was accomplished by wedge resection in 68 patients, segmental resection in 38, and lobectomy in 115. The postoperative management included bed rest and hospitalization for approximately one year. Results from excision of necrotic tuberculous pulmonary lesions were gratifying. The operative mortality was 0.5%. The incidence of postoperative tuberculous complications was 3.2%, late pulmonary reactivation 2.2%, and late extrapulmonary reactivation (axillary and cervical adenitis) 0.9%. Four patients were lost to observation, and 207 (93%) of the remaining 216 are alive and well; 75% of those operated on prior to 1952 are working. The authors' study is a retrospective one dating back to 1947, and during this period much progress was made in the treatment of pulmonary tuberculosis.

Sublingual Administration of Curare.—Neff and Mayer point out that the relatively short duration of action produced by the intravenous administration is desirable when curare is used in anesthesia and neuropsychiatry. When curare is used in diseases in which spasm of the voluntary muscles is a feature, however, a long, continued but lower level of curarization is desirable. In order to achieve this, it was decided to resort to sublingual administration, which had been originally suggested by Erdei of Toronto. The first preparation used by Neff and Mayer was in the form of sublingual pellets containing 2 mg. of *d*-tubocurarine per pellet. The pellets now used contain 3 mg. of *d*-tubocurarine and, when administered sublingually, disintegrate in from 20 to 30 minutes. Sublingual administration of curare was used in patients with painful muscle spasm, who were refractory to both narcotics and mephenesin. One patient had episodes of severe back pain and muscle spasm after laminectomy; opiates afforded only partial relief, and mephenesin did nothing. Sublingual administration of curare relieved the muscle spasm and pain. In another patient with fracture dislocation of the neck, who was completely paralyzed below the seventh cervical vertebra, recovery was complicated by paroxysms of muscle spasms in both lower extremities. Narcotics gave only partial relief, and mephenesin gave no relief. Sublingual administration of curare provided sufficient relief to permit the complete withdrawal of narcotics. Contractions still occurred, but they were less severe and no longer associated with severe pain. The dose of curare needed to bring this about was 12 mg. four times daily and sometimes once during the night. The patient placed two 2 mg. pellets under his tongue and repeated this at 20 minute intervals until a total of six pellets (12 mg.) had been taken. Orders were given not to swallow or talk during the administration. When the drug was taken sublingually in therapeutic dosage by the authors (in the absence of any clinical lesion) no subjective effect whatsoever was noted. The method proved valuable also as an adjunct; for instance, it relaxed cervical muscle spasm in torticollis resulting from partial subluxation, prior to neck traction. It alleviated the symptoms of the scalenus anticus syndrome, averting in many cases the need for severing the muscle. The drug is also of value in differential diagnosis; for instance, in determining whether pain in neck or back is due to muscle spasm from nervous tension or to organic changes. Puzzling abdominal pain may be explained since the drug will relieve pain caused by abdominal muscle spasm from a rectus tear or strain, but will not influence the smooth muscle spasm of uterine cramps or a bowel lesion. Although the drug works best on muscles that are palpably in spasm, it also relieved pain caused by intramuscular injection of meralluride (Mercuhydrin). In general, the sublingual administration of curare was more effective than mephenesin.

Reactivation of Rheumatic Fever After Mitral Commissurotomy.—Of 179 consecutive patients who underwent mitral commissurotomy, 67 had recurrent chest pain after discharge from the hospital; 43 (24%) had a febrile syndrome characterized by the appearance of an episodic recurrence of a combination of events first occurring after a variable latent period after the surgical intervention. It was uniformly characterized by precordial pain and fever, frequently associated with precipitation or intensification of heart failure and was at times accompanied by migratory joint pains, arrhythmias, hemoptysis, or psychosis. It terminated in death in three patients. The syndrome is regarded as a reactivation of rheumatic fever because of its frequency after mitral commissurotomy and its absence after any other nonrheumatic cardiac or pulmonary surgical intervention and because of the frequent cardiac involvement. The authors believe that the incidence of this syndrome is even greater than that reported in this paper because (1) the incidence in those patients they had the opportunity of following personally is higher, (2) they have seen in consultation several patients in whom fever was not recognized because the temperature was either not taken (the pain was regarded as of incisural origin) or taken incorrectly, and (3) several of the referring physicians were using large amounts of salicylates routinely after hospitalization, a practice that the authors approve.

Antibiotic Therapy of Bacterial Endocarditis.—Short-term combined treatment with penicillin and dihydrostreptomycin for two weeks was given to 16 men and 7 women with subacute bacterial endocarditis caused by penicillin-sensitive streptococci. A low-grade fever, malaise, anorexia, tiredness, and weakness characterized the illness of most. The presence of a heart murmur was the clue to the source of the patient's difficulty. Rheumatic heart disease was present in 18 patients, degenerative or "arteriosclerotic" heart disease in 3, and syphilitic heart disease with syphilitic aortic insufficiency in one. In one patient, it was not possible to state whether any preexisting heart disease was present. Anemia, noted in 15 of the 23 patients, was mild in 12 and moderate in 3. The values for hemoglobin ranged as low as 6.2 gm. per 100 cc. of blood and averaged 10.3 gm. Leukocyte and differential counts were abnormal in only a few patients. Eighteen patients (78%) remained well during follow-up periods of from 3 to 24 months. No therapeutic failures or relapses occurred in the living patients. Five patients (22%) died. Four of the deaths were due to complications of the endocarditis and the underlying heart disease, namely, congestive heart failure and cerebral embolism, while the fifth was due to coronary occlusion with myocardial infarction. One million units of aqueous procaine penicillin G and 1 gm. of dihydrostreptomycin sulfate given intramuscularly every 12 hours for two weeks represent adequate and curative treatment for subacute bacterial endocarditis caused by penicillin-sensitive streptococci.

Peritoneal Factor in Sterility.—Murray feels that the tubo-ovarian space, which is covered by peritoneal serosa and connects the surface of the ovary with the abdominal end of the tube, is a part of the ovular migration system and must be considered in the study of sterility in women because a lesion in this space may interfere with follicular ripening, ovulation, migration of the ovum to the tube, and the reception of the ovum by the infundibulum of the tube. Such lesions are similar to tubal obstruction in their consequences and are designated as pelvic blockage. The author has been concerned with this aspect of sterility for more than 10 years and has found pelvic blockage in 234 of 2,017 patients (11.6%) examined. Pelvic blockage may be the result of anatomic and functional factors. Anatomic blockage may be of the following types: ovarian, tubal, simple peritoneal, noncommunicating sacciform peritoneal, and communicating sacciform peritoneal. The cause of functional blockage lies in the fixation and retraction of one or other organ or in muscular or nervous lesions that interfere with the approximation movement of the tubal infundibulum to the ovarian surface. These processes are usually due to inflammation of the pelvis from postabortion or puerperal septic infections, gonorrhea, and genital tuberculosis. Other pathogenic factors are surgical trauma and its sequelae, external endometriosis after intrauterine maneuvers, inflammation of the neighboring organs, and peritoneal irritation caused by foreign substances (sulfonamides). In the diagnosis of pelvic blockage, gynecologic examination may have to be supplemented by hysterosalpingography, kymographic persufflation, laparoscopy, and culdoscopy. Medical therapy is similar to that of tubal obstruction, and includes the use of estrogens, diathermy, tubal persufflation, vitamin A, and, finally, cortisone, because of its action on connective tissue. With the aid of such measures, the author obtained some satisfactory results, in that 18 pregnancies resulted among 168 treated patients. When clinical measures have proved useless, surgical treatment may be necessary to remove adhesions, bands, septums, and hypertrophic scars; for peritoneal reconstruction of raw surfaces; and for the approximation of the ovary to the ostium of the tube. The results obtained with surgery were not outstanding because of the irreversible nature of many of the conditions or their tendency to recur. The intrauterine or peritoneal use of penicillin may prove of prophylactic value. In experiments on rats, a reduction of cicatrization was obtained with the use of cortisone and corticotropin, but, in humans, their use is still in the experimental stage.

Storage of Blood Below 0 C (32 F) in Liquid State.—Lorant and associates point out that the importance of refrigeration in the preservation of blood was recognized by Rous and Turner in 1916. The temperatures most suitable for survival of human red blood cells were found to lie between 4 and 9

C (39 to 48 F) with an optimum at about 7 C (44.6 F). Temperatures above 10 C (50 F) favor more rapid deterioration of erythrocytes. Storage temperatures below 0 C could not be evaluated because blood freezes and then hemolyzes completely on melting. At temperatures below freezing, blood can be kept liquid by the use of high pressures and by ethyl alcohol. Investigations on the preservation of blood with these aids revealed that the damage caused by pressure in the range investigated was considerable. High pressure, low temperature preservation of whole blood does not seem to be a promising procedure for long-term mass preservation of whole blood. The presence of 21% ethyl alcohol in the blood permits storage of whole blood at -12 C (+10.4 F) in the liquid state. At this temperature 21% alcohol does not hemolyze red blood cells. The spontaneous hemolysis in blood, kept from freezing by alcohol and dextrose after four months' storage at -12 C, was equal to, or slightly less than, in blood stored at 4 C in A-C-D (anticoagulant acid citrate dextrose) solution alone. Osmotic resistance of the red blood cells showed a definite, but not remarkable, improvement in the blood stored at -12 C in alcohol. It is urged that the use of alcohol for the low temperature, long range storage of blood and other tissues be studied.

*Fatal Cardiac Complications During Electroshock Treatment: Case Report. N. Malamud and A. Zheutlin.—p. 458.

Fatal Cardiac Complication During Electroshock Treatment. —After citing earlier reports on fatalities from electroshock treatment, which has been estimated at 0.5 or 0.8 per 1,000 cases, Malamud and Zheutlin report what they believe to be the first instance of rupture of the heart associated with electroshock therapy. The patient was a 55-year-old woman. Death was obviously due to cardiac tamponade that resulted from bleeding into the pericardial sac produced by the rupture of the myocardium at the site of infarction. Microscopic study indicated that the infarct was approximately of four to six days' duration, and it is, therefore, evident that this lesion antedated the fatal episode. The occurrence of myocardi infarction after electroshock treatment has been explained Altschule and Tillotson as the result of additional work bei required of the heart after the convulsion to overcome t accumulated oxygen debt. This mechanism seemed to pl an important causative role in this case in so far as the ru ture of the heart was concerned, even though the actual my cardial infarction was the result of coronary occlusion. has been suggested that the critical period in the course of myocardial infarction occurs during the second to sixth d when the greatest amount of necrotic tissue is present and t myocardium is the weakest. In this case the combination weakened myocardium with a four to six day old infa plus the increased demand on the heart produced by elect shock probably resulted in the rupture of the myocardiu It is suggested that acute coronary occlusion at a cert critical stage should be regarded as a contraindication electroshock therapy.

*Emergency Pulmonary Resection for Massive Hemoptysis in Tuberculo C. A. Ross.—p. 435.

Emergency Pulmonary Resection for Massive Hemoptysis.- A successful emergency pneumonectomy was performed f massive hemoptysis in a woman aged 45 with pulmona tuberculosis involving the right lung. On admission of t patient to the sanatorium, one month before the surgical inte vention, roentgenograms showed that the upper lobe w fibrotic and contained a large cavity while the lower lo showed scattered nodule formation and fibrosis. The sputu was positive for Mycobacterium tuberculosis. Resection w considered but postponed because the patient was not co sidered fit for surgery, and a pneumoperitoneum was induce in an attempt to improve her condition. Several weeks late after a rather large pneumoperitoneum refill, she began cough up bright red blood; the hemorrhage became profus and for four days she had repeated hemoptyses varying fro 10 to 20 oz. of blood at a time. A transfusion of 500 cc. blood was given. A diffuse spread of the disease to the low lobe of the right lung was demonstrated on roentgenolog examination. Five days later she had further profuse hemo tysis resulting in extreme shock. Further transfusion w started, but replacement did not keep pace with the continue loss of blood. It was then that the emergency pneumonectom was performed. She received a total amount of 8,000 cc.

blood, including the two bottles that were running at the time she was taken to the operating room. Dihydrostreptomycin therapy with a dose of 1 gm. daily was started eight days before the surgical intervention and was continued with reduced doses for four months combined with *p*-aminosalicylic acid in doses of 12 gm. daily. A definite contralateral spread of the disease was noted on the sixth postoperative day. Three weeks after the operation isonicotinic acid hydrazide was started in doses of 200 mg. daily, and combined treatment with this drug and with *p*-aminosalicylic acid was continued for seven months. A solution of *p*-aminosalicylic acid containing 10 gm. of the drug was introduced into the right pleural space every other day for two weeks postoperatively. A small pneumoperitoneum was maintained for five months postoperatively to help reduce the size of the right hemithoracic space. The patient was discharged from the sanatorium after eight months. She was steadily gaining weight, and roentgenograms did not show any evidence of active disease in the contralateral lung. Though the operation was performed during an acute exacerbation of the tuberculous process and on a patient who was a very poor surgical risk, the outcome was gratifying. A contralateral spread of the disease appeared to be controlled by prolonged antibiotic therapy. Technical considerations of importance are as follows: excellent anesthesia is most necessary; large amounts of blood must be given, particularly during the operation; endobronchial tamponade prior to beginning surgery is the ideal method of positively controlling the hazard of aspiration of blood by the other lung; speed in surgery is necessary; prolonged antibiotic therapy is required in addition to surgical intervention. Conservative measures should first be tried to control the situation, but surgery should not be delayed until a massive contralateral spread of the disease has occurred or the patient is in such poor condition as to be beyond surgical help.

Trigeminal Symptoms in Acoustic Nerve Tumors.—Analysis of large groups of cases of acoustic nerve tumors and a review of 35 cases observed by the authors reveal that trigeminal symptoms are present in the majority. The authors give a detailed history of one patient in whom the major symptom of facial numbness became so acute and bothersome that surgical removal of a small acoustic neurofibroma was accomplished. If the facial numbness had not been so marked, it is probable that the tumor would have grown much larger before causing other symptoms necessitating or bringing about surgical removal. The presence of facial numbness and particularly corneal anesthesia, as demonstrated by loss of the corneal reflex in association with the symptoms referable to the eighth nerve, should immediately call attention to the probability of the existence of a relatively large tumor in the cerebellar pontine angle on the affected side. Otological examination should seldom fail to establish the diagnosis in the presence of the above mentioned symptoms. The diagnosis and surgical treatment of acoustic nerve tumors in a relatively early stage will lead to a high recovery rate with a minimum of residual symptoms.

Chronologic Account of Meeting Places of Massachusetts Medical Society and Its Council. F. R. Ober.—p. 482.

Toxicity of Oxytetracycline (Terramycin).—Observations on the clinical toxicity of oxytetracycline (Terramycin) were made on 70 tuberculous patients receiving 5 gm. of the drug daily in combination with 2 gm. of streptomycin every third day, both drugs being given for 120 days. In this group, as in a group of 27 treated earlier with oxytetracycline, no ototoxic, nephrotoxic, hepatotoxic, avitaminotic, dermatological, or hematological changes were noted. The signs and symptoms of gastrointestinal tract irritability were the only clinical manifestations of toxicity. Anorexia was the commonest symptom, occurring in 70% of the patients. It usually persisted throughout the four month period of treatment. Nausea, the second commonest symptom, occurred at least once in 50% of the patients. It was sporadic and transient as a rule. There were four patients, however, in whom nausea was more or less persistent. Vomiting was observed at least once in 9 of the 70 patients studied. In four cases it persisted when 5 gm. was taken. All four patients, 2 of whom were women, were able to continue taking oxytetracycline by either reducing the dosage or taking the drug intermittently. The occurrence of one to four soft stools per day was observed in 70% of the patients, usually throughout the period of therapy. A few of the patients experienced a mild diarrhea. Patients who experienced nausea, vomiting, and diarrhea were examined by proctosigmoidoscopy, but no abnormalities were found. Contrary to many reports in the literature, observations on this series indicated that the gastrointestinal tract irritation due to oxytetracycline is not a serious problem since no patient had to stop taking the drug during the four months of administration, and only four had to have the dosage reduced.

X-Ray Diagnosis in Disorders of Biliary Tract. A. J. Tillinghast.—p. 750.

Medical Treatment of Chronic Ulcerative Colitis.—Morrison presents a three point program of medical treatment of chronic ulcerative colitis. It includes: (1) oral administration of salicylazosulfapyridine; (2) oral administration of cortisone or the intramuscular use of corticotropin (ACTH); and (3) psychotherapy. He reviews several previous reports on the use of salicylazosulfapyridine in ulcerative colitis, including his own experience with this drug in 52 patients over a three year period. The dosage was 1.5 gm. (3 tablets) every three hours for two weeks. After a rest of two weeks, the course may be repeated once or twice if needed. The drug is deposited in the connective tissue of the intestine where aminosalicylic acid and sulfapyridine are gradually liberated; it acts locally and then undergoes some absorption into the blood where acetylsulfapyridine and free sulfapyridine are found. The customary measures, such as proper dietary control, rest, supplemental vitamins and palliative drugs, maintenance of fluid and electrolyte balance, are continued during the treatment with salicylazosulfapyridine. Patients who do not respond are then given intramuscular injections of corticotropin in the form of a gel and in doses of 40 to 200 mg. once daily or cortisone by mouth in doses of two tablets (50 mg.) two to four times daily. The majority of patients experience a rather prompt remission with disappearance of the acute inflammatory reaction in the colon, a feeling of well-being associated with improvement in nutritional status, reduction of diarrhea and of bloody stools, and increase in appetite. If a relapse occurs, resumption of the administration of corticotropin or cortisone usually again produces remission. Close observation is necessary during the administration of these hormones because of the danger of serious complications. Most patients with chronic ulcerative colitis need supportive psychotherapy. The patient is encouraged to discuss his life, aggressive feelings, and social difficulties in a series of interviews, the physician playing the role of the sympathetic parent ministering to the patient's needs. These needs arise from insecurity and oversensitivity, aggravated by the debilitating effects of chronic abdominal pains, diarrhea, and bloody, purulent stools.

Treatment of Chronic Discoid Lupus Erythematosus.—Fourteen patients with chronic discoid lupus erythematosus were treated, 10 receiving quinacrine hydrochloride and 4 chloroquine phosphate. The dosage of quinacrine hydrochloride consisted of 300 mg. daily for the first week, 200 mg. daily for the second week, and 100 mg. daily for the third week, until objective improvement in the lesions appeared. The first dose of chloroquine phosphate was 300 mg.; this was repeated after 6 hours and then after another 12 hours. Later it was given in 150 mg. doses three times a week. Of the 10 patients receiving quinacrine, 6 showed definite improvement, 3 slight improvement, and 1 a progression of the lesions. In four patients receiving chloroquine, one showed slight improvement and 3 little or none. The time elapsed is too short to predict how long the clinical remission will be maintained. The mode of action of quinacrine may be explained in one of three ways: (*a*) reduction in light sensitivity of the skin; (*b*) an action similar to that of corticotropin and cortisone, or (*c*) by antagonizing adenyl compounds in the chronic discoid lupus erythematosus lesions.

Pulmonary Resection in First Year of Life.—Pulmonary resection was performed on six infants between the ages of two and eight months. Three had congenital pulmonary cysts for which lobectomy was performed in two and local resection in one; one had chronic, irreversible atelectasis; and two had bronchiectasis associated with cystic pancreatitis. In a seventh infant reported on previously by one of the authors, a right middle lobectomy was done because of localized hypertrophic emphysema. A five to six month follow-up of the three patients with cystic disease showed that the infants were developing normally with no evidence of respiratory difficulty. A follow-up was unobtainable in the case of the infant with atelectasis. A six week follow-up of the patient with localized hypertrophic emphysema showed normal expansion of the right lung and normal position of mediastinum. Although resection of the atelectatic and bronchiectatic lobes failed, in the remaining two patients, to improve the pulmonary complications associated with cystic pancreatitis sufficiently to bring about a long survival, it is believed that pulmonary resection is rational in this condition. With the advances made in anesthesia, technique of pulmonary surgery, antibiotics, and the knowledge of respiratory physiology, it is now possible to perform pulmonary resections in infants with a high degree of safety.

Shunt Operation for Portal Decompression.—Of 30 patients with portal hypertension and esophageal varices operated on, the causative obstruction of the portal bed was intrahepatic in 28, Laennec's cirrhosis in 21, postnecrotic cirrhosis in 6, and biliary cirrhosis in 1; extrahepatic block accounted for portal hypertension in only 2 patients with Banti's syndrome. Regardless of the exact mechanism responsible, some type of portal decompression must be utilized, if rupture of esophageal varices causing massive hematemesis with resulting deaths in as many as 70% of all patients with portal hypertension are to be prevented or significantly decreased. The direct end-to-side portacaval shunt is the operation of choice and was employed in 22 patients. The splenorenal shunt was established in five patients. Neither shunt could be established in the remaining three patients, and less desirable procedures were utilized. A thoracoabdominal incision was used exclusively. The Potts coarctation clamp and the Potts giant bulldog clamp are recommended for use on the portal vein and inferior vena cava respectively. Only two of the 30 patients died postoperatively, and both deaths occurred from liver failure. The alterations in postoperative liver function were mild, lasting from 7 to 10 days, when the operative time was minimal and intravenous chlortetracycline (aureomycin) was used routinely. Complete diversion of the portal blood did not interfere with the hepatic function in patients followed up to three years. Preoperative and postoperative manometric pressure readings in the esophageal varices are recommended in all patients to evaluate the operation. These pressures correlated closely with those obtained in the portal vein before and after operation. The portal circulation time, obtained by using the ether technique, indicated patency of the shunt and also correlated with the various pressure readings. Studies indicated that the systemic caval pressure influenced the degree of portal decompression obtained after operation. With follow-up from one month to three years, only two minor hemorrhages occurred after adequate portal decompression. Shunt operation was employed in six patients with severe portal hypertension and esophageal varices who had not had any previous episode of hemorrhage; there were no postoperative hemorrhages in the group. Percutaneous splenic and portal venography offered valuable diagnostic aid in determining the configuration of the portal vein prior to surgical intervention and in determining the patency of the shunt postoperatively.

Carcinoma of the Breast.—The results of simple and radical mastectomy with and without primary x-ray therapy in 739 consecutive and unselected women treated between 1905 and 1946 and followed up for from 5 to 20 years were subjected to critical analysis concerning the relationship of primary x-ray therapy, age at the time of surgical intervention, and prophylactic castration to the length of survival. According to these analyses, primary x-ray treatment in conjunction with mastectomy had prolonged the life among patients with axillary metastases. From a separate study of patients with grade 2 and grade 3 cancers of the breast, evidence was obtained that only patients with grade 3 tumors were benefited by x-ray therapy. In this group, moreover, the higher rates of survival were observed not only among those with involvement of axillary nodes but also among those without such involvement. The lowest percentages of survivors were among women between the ages of 40 and 60, that is, during the premenopausal and postmenopausal climacteric, suggesting that changes referable to the physiological involution of the ovaries augment the clinical malignancy of mammary cancer. Prophylactic ovariectomy prolonged life not only in women less than 40 years of age and over 59 but more so in those 40 to 59 years of age. There was some evidence of lengthened survival from prophylactic x-ray irradiation of the ovaries. The improved percentages of survival among the patients subjected to prophylactic ovariectomy were high enough to indicate that prophylactic ovariectomy deserves more extensive trial in women up to 70 years of age with axillary metastases if they can be persuaded to undergo a second major operation; the amount of benefit in each patient is as yet unpredictable. If, however, the growth of a given cancer of the breast should be amenable to retardation by the removal of ovarian stimulation, it would seem that the earlier ovariectomy is performed the longer will be survival. The authors' statistical analyses are given as suggestive but not conclusive evidence in favor of the findings.

Fraction of Commercial Yeast Which Protects Against Bacterial Infection: Preliminary Note. I. A. Parfentjev.—p. 75.

Fraction of Yeast That Protects Against Bacterial Infection.—There are indications that vaccination with Hemophilus pertussis, while increasing resistance against infection by this organism, will, at the same time, produce hypersensitivity to the H. pertussis antigen. Such sensitivity, however, is not specific for pertussis but crosses with several other species of gram-negative bacteria. Furthermore, mice immunized against pertussis are much more susceptible to infection by other gram-negative bacteria than are their normal litter mates. Apparently, specific immunization can produce a nonspecific lowering of resistance that predisposes the host to unrelated infections. Because bacterial protein plays a part in hypersensitivity and is implicated in the etiology of infections, the search for a desensitizing protein was undertaken. The obvious selection was protein associated with the nucleic acid of the bacterial cell from the specific Hemophilus organism. Injection of this material reinforced the resistance of sensitized animals. However, since hypersensitivity is not species specific, the possibility of another source of comparable material was apparent, and it was found that a preparation of yeast sodium nucleate would not only reduce the hypersensitivity of vaccinated animals to the same pertussis antigen, but make them refractory to gram-negative bacteria. Numerous experiments proved that mice after injection with sodium nucleate are protected against infection by Proteus, Pasteurella, Brucella, and Escherichia coli organisms. Subsequent studies indicated that different brands of sodium nucleate were variable in potency. The source material, yeast, was fractionated in search of the active principle. A very potent fraction was isolated from baker's yeast, which is over three-hundred-fold more effective than commercial preparation of sodium nucleate and will protect animals against infection with gram-negative bacteria.

Use of Phenylethylacetylurea in Treatment of Epilepsy. L. Sorel and R. De Smedt.—p. 531.

Histopathology of Multiple and Diffuse Sclerosis.—Multiple sclerosis in its diverse forms is an encephalitis marked by foci of specific demyelinization affecting the myelin sheaths, the axons and neurons being spared. The foci arise by diffusion of a myelinolytic substance from small blood vessels or from tissue liquids without regard to preexisting structures. The foci are distributed throughout the nervous system in general, although areas of predilection can be found. There are simple and concentric foci. Some surprising analogies have been found between human multiple sclerosis and the ringspot diseases of plants. 1. Both display the same kind of concentric foci, the same kind of simple continuous foci, and the combination of the two types. 2. These foci arise by simple or rhythmic diffusion of a constantly multiplying agent of infection; in plants, this agent has been proved to be a virus. 3. The concentric arrangement of the foci is thought to be due to the repeated appearance of intratissue defensive substances. Substances hostile to the virus have been isolated in afflicted plants. 4. In both diseases the foci are distributed haphazardly throughout the organism, but also have areas of preference. 5. Distribution is achieved by way of the parenchyma and vessels in both and is comparable in terms of time and space. The agent of infection can pass through only the smaller vessels, which, incidentally, it does not attack. 6. The disease is associated, in either case, with a particular tissue and thus with a particular organ. There appears to be no connection between multiple sclerosis and any of the other encephalitic diseases. Experimental allergic encephalitis does not show specific demyelinization and so cannot be compared to multiple sclerosis. Among the spontaneous diseases of this type in animals, only multiple sclerosis in the dog has histopathological characteristics suggestive of human multiple sclerosis.

Necrotic Arachnidism.—Necrotic arachnidism consists of a cutaneous necrosis, progressing to dry gangrene at the site of the bite, fever, jaundice, hemoglobinuria, cutaneous and intestinal hemorrhages, exanthema, and hemolysis. It is a serious condition and is fatal in a high percentage of children. A spontaneous regression of the acute symptoms occurs between the fifth and seventh days; local necrosis follows a slowly regressive course. From 1938 to 1949, 29 cases have been reported in the Uruguayan literature; the authors add three new cases. The disease was acute in eight patients. Three patients were children between the ages of 6 and 11 years. Two died 30 and 36 hours after the bite. The spiders were captured in the act of biting in two cases. They were identified as females of the Loxosceles laeta species. In the remaining cases the spider was either killed by the family of the victim or its type was not mentioned by the authors. Loxosceles laeta spiders are common in certain cities of Uruguay and other countries of South America. Their bite produces the necrotic, eruptive, and icterohemolytic forms of arachnidism. The authors made experiments on a large number of Loxosceles laeta spiders with the following results. Mice usually die within 24 hours after the bite or after a subcutaneous injection of the poison. They die with symptoms of general poisoning and paralysis of respiration. Rabbits usually die within 24 hours after the bite or after the subcutaneous or intradermic injection of the poison. They die with symptoms of general poisoning. The bites of one or two spiders are necessary to cause death in rabbits, according to the weight of the animal. Degeneration of the hepatic and renal cells and necrosis of the epithelium of the large intestine were observed in mice. The fatal dose of the poison is very close for mice and rabbits. In guinea pigs, the necrotic local lesion is the only effect observed. The female Loxosceles laeta, and not the male spider, proved to be the one that caused death of mice and rabbits and the one that contains in its glands enough poison to kill four or five mice or rabbits. The serum of immunized rabbits proved to protect mice against at least one mortal dose of the poison, even if the serum was given to the animal four hours after inoculation of the poison. The serum of nonimmunized rabbits and other antiarachnid and antiophidic serums did not protect mice against the poison. Prevention of necrotic arachnidism depends on cleanliness of housing and the use of benzene hexachloride as an insecticide.

Experiences with Chemical Pregnancy Test.—According to Benthin and von Törne attempts to demonstrate pregnancy by chemical means have not been convincing. This applies to the histidine method, as well as to the pregnanediol test. The iodine boiling test of Schlör seemed to be somewhat superior to these tests, not only in reliability but even more in simplicity. The authors, in performing the biological Galli Mainini test, which utilizes male toads, on 145 urines submitted to them for pregnancy tests, also made Schlör's chemical test on the same urines. The Schlör iodine boiling test yielded 17 negative reactions in 74 established pregnancies (23%) and 14 positive reactions in 71 urines (20%) of nonpregnant women. These percentages of erroneous reactions correspond closely to those obtained by others with the Schlör test. The authors conclude that the iodine boiling test cannot be regarded as a reliable indicator of pregnancy. Modifications of the original method did not noticeably improve the results.

Ammonia, Urea, and Uric Acid in Renal Insufficiency and Gout.—The toenails of 11 patients with various types and degrees of renal impairment, but all with markedly increased blood urea levels at the time of death, were examined for water extractable urea, ammonia, and uric acid. The urea content of these toenails was always elevated. The ammonia content did not exceed normal values. The uric acid content of the toenails was markedly elevated in patients with chronic nephritis, but it was normal in those with renal impairment of short duration. In a patient with long-standing severe gout who died from interstitial nephritis, the uric acid content of the toenails was about four times as high as that from normal persons. For the estimation of the nonkeratin uric acid content, 50 mg. of nail are required; this amount can readily be obtained by means of nail parings from living subjects. Thus, it became possible to evaluate the uric acid content of toenails and fingernails and of head hair of three patients suffering from gout uncomplicated by renal insufficiency. They all showed definitely increased uric acid values in nails and head hair, while the blood uric acid content was normal at the time. This observation suggests that uric acid determinations on the readily available keratinous appendages and particularly toenails may be of diagnostic value. The elevated uric acid values found in gout, and to a lesser extent in chronic renal insufficiency, could be due either to a spilling over from other tissues into the keratinous structure as such or, in part, at least to a metabolic disturbance within the keratin-producing structures. The deposition in the keratinous structures of uric acid, which is difficult to excrete when there is renal impairment, seems feasible, particularly since the capacity of keratinous tissues to contain or fix comparatively large amounts of uric acid has been demonstrated in other mammals. In nephritic persons, uric acid formed as an end-product of the nucleic acid degradation in the process of keratinization may thus be forced into the developing keratin to a greater extent than usual. In advanced gout, moreover, considerably higher uric acid values can be obtained in toenails and hair than in chronic nephritis, though the blood uric acid levels are about the same in the two conditions. The authors are inclined to favor the view that increased deposition in gout is not due to a metabolic disturbance in the keratin-producing structures but that it is simply an excretory mechanism.

*Relaxation of Muscle Spasm in Chronic Arthritis by Prostigmin. T. H. Howell.—p. 192.

Prostigmin for Muscle Spasm in Arthritis.—One of the common syndromes among the elderly persons under treatment at a clinic for rheumatic disorders appeared to be pain associated with muscular spasm. This was found in osteoarthritis and in rheumatoid disease. The usual sites were: (1) the vastus internus muscle, secondary to arthritis of hips or knees; (2) the flexor muscles of the forearm, associated with changes in the carpus or the elbow; and (3) the trapezius muscle, often accompanying cervical spondylitis. A series of 60 outpatients, all of whom had pain from muscle spasm in one of the sites mentioned above, were given 0.5 mg. of the drug by intramuscular injection. In 38 of these, one injection was enough to relax the muscles and to relieve the pain. Among the remaining patients, 14 received two or more injections with benefit, whereas the other 8 either did not respond or were made so sick by the drug that they could not recall any relief. Only pain from muscle spasm was relieved by prostigmin; other types remained unaltered. Prostigmin was tried also in 12 patients with chronic arthritis. An injection of 0.5 mg. was given twice a week before remedial exercises, in addition to its therapeutic use for spasm. The increased freedom of movement resulting was considerable, so that the patients themselves would deliberately ask for their injections "to make them looser." The effect of the drug lasted as a rule for 8 or 12 hours and began about 20 minutes after intramuscular injection. A tendency to vomiting or abdominal discomfort is an undesirable side-effect, and seems to increase when the drug is used over long periods.

Pulmonary Adenomatosis.—The first case of pulmonary adenomatosis in the United Kingdom to be diagnosed before death occurred in a 36-year-old woman who had complained of lassitude six months before she was seen by the authors at the Hairmyres Hospital in Glasgow. She had had an attack of what was presumed to be pneumonia a month after the onset of the lassitude. The only symptom of diagnostic value was the expectoration of abundant frothy sputum. In the lobectomy specimen taken from her right lung, the disease was present in the form of multiple nodules that had coalesced to produce almost uniform involvement of the lower and medial parts of the lobe. There was no invasion of the pleura, and microscopic examination disclosed a highly differentiated epithelial neoplasm of pronounced papillary architecture and only very restricted powers of replacing the normal lung structures. Mucin formation was not a pronounced feature of the growth. After operation, the remaining portion of the right lung became involved and the disease spread to the left lung. The patient became increasingly more dyspneic and died at home six months after operation. A necropsy was not permitted, and thus the possibility of an extrapulmonary lesion was not conclusively ruled out. The clinical features and natural history of the case, however, are in keeping with descriptions in the literature and justify the diagnosis of pulmonary adenomatosis.

Percutaneous Transhepatic Cholangiography.—In this series of five patients with obstructive jaundice on whom percutaneous transhepatic cholangiography was performed by the injection of 20 ml. of 35% iodopyracet (Diodone) into a bile duct, the procedure was technically successful and clinically noncontributory in four. One patient, in whom the procedure was also technically successful, died from blood and biliary leakage into the peritoneal cavity; this fatality is attributed to failure in preparing the patient for the test with vitamin K. The radiographs obtained by this method were good and permitted a correct diagnosis. In three patients without obstructive jaundice, the procedure was unsuccessful. The authors feel that their method is valuable and should be investigated further, despite the one death. The test ought not to be any more hazardous than liver biopsy, which has been successfully performed a great many times and which requires a larger needle.

Carcinoma of the Female Breast.—An analysis is made of 1,044 cases of carcinoma of the breast in women first seen at the same hospital in the period 1930-1939. Since these patients were treated some time ago, follow-ups permit a comparison of the treatments employed. Simple surgery was undertaken in 229 cases, more than half of which were treated by simple excision of the tumor. Radical mastectomy was done in 338 cases, and a modified radical operation in 167. Radium treatment without surgery was used in 149, and x-rays alone in 114. Forty-seven cases remained untreated. Of the patients treated surgically, about two-thirds were also given irradiation. This type of treatment became more frequent toward the end of the period mentioned; at the same time x-rays tended to replace radium, particularly in combination with simple surgery. The 5 year survival rate for lesions treated in stage 1 was 72%; the 10 year rate 51%; the 5 year rate for stage 2 lesions was 39% and the 10 year rate 26%. The rates for each treatment group showed no appreciable departure from these figures despite the fact that simple surgery consisted merely of local excision in more than half the cases. The addition of irradiation did not affect the rates, although it is possible that selection of cases may have concealed some of the benefits of radiotherapy. Attention is drawn to the lower survival rates in the lesions assessed clinically to be in stage 2 but with axillary nodes uninvolved as compared with stage 1 lesions with nodes involved. The mortality of radical mastectomy was 1.2%. Edema of the arm occurred after radical surgery in 14% of the patients, compared with 5% after simple surgery. It was almost twice as frequent when the radical wound gave rise to complications as in those with primary healing. The most impressive finding in this series is the remarkable similarity in survival rates after different methods of treatment. All methods have been equally effective in stages 1 and 2; but all seem to be equally ineffective in prolonging life. It is not known to what extent treatment affected survival. A general conclusion from these data is that, where efficient radiotherapy is available, radical mastectomy should be abandoned in favor of conservative surgery.

Pulmonary Metastases from Breast Cancer.—The histories of 61 patients with pleural and lung metastases from carcinoma of the breast for whom estrogen therapy was prescribed are compared to those of 66 for whom it was not. In the treated group, 31% (19) of the patients survived over 12 months as compared with 7.5% (5) in the untreated group. In the treated group, 26% (16) of the pulmonary lesions showed regression, compared with none in the untreated group. Thirty-nine patients took estrogen for three months or more; 22 (57%) survived seven months or longer. Twenty-two took estrogen for two months or less; 4 (18%) survived over seven months. It may be that results are better with a more prolonged administration of estrogen; but regression occurred in some cases after administration of estrogen for two months. It must be assumed, therefore, that two months is adequate for the establishment of a reaction capable of controlling the disease. The effects of estrogen in these cases are essentially temporary, and no prophylactic effect against the development of pulmonary metastases can be shown.

*Role of Liver in Metabolism of Estrogenic Bodies. C. Mayer.—p. 1925.

Role of Liver in Metabolism of Estrogenic Bodies.—The fact that the metabolism of estrogens depends on the liver, an antiestrogenic organ affecting both natural and synthetic substances, is shown by various experimental data. Inactivation of estradiol, an ovarian hormone, is accomplished by the liver. It is transformed into estrone and a very weak hormone, estriol. Much more estriol than estrone is produced. The chemical transformation of estradiol into estriol is irreversible. This knowledge illuminates the clinical manifestations designated by the term "hepato-ovarian syndrome." The syndrome is present in patients with hyperfolliculinism caused by hepatic dysfunction. Awareness of this interdependent relationship should caution against the indiscriminate use of natural and synthetic estrogens that has resulted from the popularity of these hormones in recent years.

Hemorrhage During Anticoagulant Therapy.—One of four anticoagulants was assigned by random distribution to 489 patients with thromboembolic disorders treated at the Toronto General Hospital. Of the 489 patients, 112 were given heparin (10,000 units per cubic centimeter) intramuscularly. The usual dose of heparin was 150 mg. (1.5 cc.), and this was injected into the gluteal muscles every 12 hours. Maximal prolongation of the clotting time occurred within 3 to 4 hours, with a return to normal in 8 to 10 hours. Hemorrhagic complications occurred in 17 of these 112 patients. Bishydroxycoumarin (Dicumarol) was given by mouth to 123 patients; hemorrhagic complications occurred in 4. Phenindione (Phenylindanedione) was given orally to 133 patients; bleeding did not occur in any of these. Cyclocumarol was given orally to 121 patients, and hemorrhagic complications occurred in 7.

Thus 28 (5.7%) of the 489 patients suffered bleeding that was severe enough to require discontinuation of the anticoagulant therapy. There were five deaths associated with bleeding, and in at least two of these cases bleeding was the main factor causing death. A significantly higher incidence of bleeding was observed in the group receiving heparin intramuscularly than in the groups given phenindione or bishydroxycoumarin. The group receiving cyclocumarol compared unfavorably with that receiving phenindione. Vitamin K_1 and K_1 oxide were effective in correcting hypoprothrombinemia caused by anticoagulants given orally. Daily prothrombin determinations allowed oral administration of anticoagulants to be controlled with slight risk of bleeding. Clotting time determinations were less successful in the control of heparin given intramuscularly. It is possible that, with heparin given intravenously, the control is more precise and the danger of bleeding less.

Isoniazid in Childhood Tuberculosis.—Isoniazid was used for the treatment of 50 children with tuberculosis, including some with tuberculous meningitis, tracheobronchial ulcerations, miliary tuberculosis, extensive lesions of the lung parenchyma, massive mediastinal lymph nodes, pleural effusion, tuberculous pericarditis, tuberculous mastoids, and persistent bacillary positive sinus from a hip. The dose of the drug used up to the end of May, 1952, was 3 mg. per kilogram of body weight. This was increased to 10 mg. per kilogram of body weight after the May, 1952, meeting of the American Trudeau Society. This dose was maintained for from two to four months without toxic symptoms in most of the patients. It was usually reduced to 5 mg. per kilogram of body weight at the end of this time, or sooner, if anorexia developed. Results showed that most human tubercle bacilli are sensitive to isoniazid and do not lose this sensitivity for months. Oral administration produced good plasma levels and, in the presence of meningitis, good spinal fluid levels. There seems, therefore, no indication for parenteral treatment. The drug produced rapid initial beneficial effects, such as weight gains, drop in erythrocyte sedimentation rate, and defervescence in most patients; these were not always maintained and other drugs had to be added later. Cortisone-like effects, or adrenogenic ones, were noted fairly often; they were pronounced in a few cases. The drug may cause increased ketosteroid excretion over a period of months. Isoniazid should not be used without streptomycin in patients with tuberculous meningitis; in early cases of the disease isoniazid may eliminate the necessity for intrathecal therapy when combined with streptomycin given by the intramuscular route alone. Isoniazid should not be used in far advanced cases of meningitis because of its additional disturbing effect on the electrolyte balance and its tendency to produce convulsions. To date, tracheobronchial ulcerations showed the most striking improvements of any type of tuberculosis in children. The characteristic "wheeze" disappeared rapidly, and the ulcers healed within three to six months.

Tuberculosis of Superficial Lymph Nodes.—Of 9,218 patients treated at the Toronto Hospital for Tuberculosis in Weston, Ontario, between 1932 and 1952, 210 (2.3%) had tuberculosis of the superficial lymph nodes. The highest age incidence was in the age group between 15 and 29 years, and there were only 30 patients less than 15 years of age. As infection with the bovine bacillus through milk has now been virtually eliminated from the province of Ontario, tuberculosis of the lymph nodes is no longer predominantly a disease of childhood, but its maximum incidence follows the incidence of tuberculosis in general. Associated tuberculosis in other parts of the body occurred in 185 (88%) of the 210 patients, most commonly in the lungs (161 patients) and bones and joints (46 patients), and this greatly affected the end-results of treatment. Of the 210 patients, 25 were North American Indians and Eskimos who showed the usual low resistance to the disease. Cervical lymph nodes were involved in 194 patients (92%), and 39 of these had generalized involvement of the lymph nodes in the neck, a condition resulting from unhindered lymphatic spread from node to node rather than from blood stream dissemination. Twenty-one of the 39 patients died, indicating an unfavorable prognosis in generalized involvement of the lymph nodes, though the disease in the lymph nodes itself is very rarely the cause of death. Diagnosis by microscopic examination of the tissues may be very difficult and bacteriological proof is the only certain proof. Best results were obtained by long-term intermittent treatment with streptomycin (1 gm. twice a week) combined with daily administration of 10 gm. of *p*-aminosalicylic acid. Any residual mass or sinus may be excised by local resection when the disease has become stationary or quiescent. Isoniazid was not used long enough for evaluation of its effect. Forty-eight patients (23%) died of some form of tuberculosis while in the sanatorium; most of these died before streptomycin became available. At present the mortality is much lower. There will be recurrences after adequate treatment in only 1 to 2% of the patients.

Renal Glycosuria and Diabetes Mellitus.—Sixty patients with renal glycosuria were followed up for 2 to 36 years. The duration of the disease exceeded eight years in 47 of the 60 patients. Six of the patients died, but symptoms of genuine diabetes mellitus were not manifested up to the time of death. The causes of death were bone sarcoma, perforating ulcer, coronary thrombosis, apoplectic stroke, ileus, and decrepitude. Follow-up revealed that the glycosuria continued constantly for many years. In rare cases it disappeared completely. Blood sugar curves were normal and did never show an elevated level after a second dose of dextrose given by mouth one hour after a first dose. Subjective complaints such as thirst, fatigue, and pruritus were mainly functional and became less with advanced age. Progression into genuine diabetes mellitus was not observed in any of the 54 patients who survived. The simultaneous occurrence in one person of a gene for renal glycosuria and one for diabetes mellitus is possible but rare. Genuine pancreatic diabetes may be manifested in the course of renal diabetes; these occurrences are independent of one another; therefore, one cannot speak of a progression of renal glycosuria into diabetes mellitus. Renal glycosuria is caused by a hereditary disturbance of the central organ that regulates the internal secretion, resulting in a secondary failure of the cells lining the proximal convoluted tubules of the kidneys to reabsorb the glucose.

Vitamin T (Goetsch) in the Care of Newborn and Premature Infants.—Schmidt presents observations on the use of vitamin T (Goetsch) in 28 premature infants and in 52 full-term infants with retarded development. The commercially available vitamin T preparation employed in this study had been demonstrated to contain vitamin B_{12}, folic acid, citrovorum factor (folinic acid), and Lactobacillus bulgaricus factor. In contradistinction to other investigators Schmidt did not commence with very small doses, but administered 5 drops twice daily of the vitamin T preparation even to weak premature infants. Older infants were given 10 drops twice daily and later sometimes 10 drops 3 times daily. The drops were usually given in milk. In one premature infant (weight 1,300 gm.), treatment was continued for eight weeks, but most of the other children received the vitamin T for only from 9 to 21 days. The results obtained were favorable, in that newborn with fluctuating or flat weight curves showed a tendency to increase in weight. The vitamin preparation was well tolerated, the stools remained normal, and no intestinal disturbances resulted, even in the weakest premature infants. The weight increase obtained under the influence of vitamin T medication in premature and poorly developing full-term infants compared favorably with that of a control group of normal infants.

New Indications for Hypophysial Roentgen Therapy of Diabetes.—The author observed in previous work that *p*-oxypropiophenone, given to 29 patients with diabetes mellitus, produced hypoglycemia in almost all of them. Hypoglycemia was marked in patients with insulin resistance and in obese hypertensive patients with insulin sensitivity. The effects of the drug were transient. The author believes that hypoglycemia following administration of *p*-oxypropiophenone is due to inhibition of the secretion of glycemia-stimulating hormones, which are overproduced when the hypophysial factor is predominant in diabetes. The method for determining indications for roentgen therapy includes the following steps. Blood is taken from a fasting patient, and the level of glycemia is determined. Immediately after taking the blood, a dose of 1.5 gm. (six tablets of 0.25 gm. each) of *p*-oxypropiophenone is given to the patient by mouth. Half an hour later and for three consecutive hours, blood is drawn at intervals of 30 minutes and the curve of glycemia recorded. If at any time in the course of this procedure, glycemia falls 15% or more in relation to the level of fasting glycemia, a predominant hypophysial disorder in the origin of diabetes and the probabilities of good results from hypophysial roentgen therapy in the given case are indicated. Good results of hypophysial roentgen therapy last longer and are more constant than those of *p*-oxypropiophenone.

Epidemiology of Canicola Fever.—Surveys have shown that from 25 to 40% of dogs reveal evidence of past infection with Leptospira canicola, and, as the carrier state in dogs may last as long as 4½ years, the potential sources of infection must be considerable in most areas. Several explanations have been advanced for the small number of reported human cases in relation to the high rate of dog infection. It has been argued that L. canicola has a low virulence for man and that for human infection to occur very close contact with the dejecta of infective dogs is necessary. It has also been suggested that the incidence in man is higher than is realized and that many cases of human disease are unrecognized. During 1951 all cases of canine leptospirosis, which had been fully investigated at the Veterinary College in Edinburgh, were used as the basis for an inquiry. The owners of dogs that had been recently ill or that were attending for follow-up after earlier infection were asked to give the name of their family physician. After consultation with the practitioners concerned, the families were visited. An inquiry into the home circumstances surrounding the illness of the dog was made, particularly in relation to soiling of the floor by urine and other dejecta. The history of illness among human household contacts was also obtained and the contacts were asked to agree to serologic examination and to submit a sample of urine for analysis. Altogether 137 household contacts were examined and blood samples from 99, or 72.3%, were tested for agglutination against L. canicola. All serums were normal. The results of the present survey and the experience with some reported cases of human canicola fever show that there is great variation in the risk of infection to owners and others living in the same house with diseased dogs. Some other source of infection common to man and dog seems possible. Dog owners should be made aware of the possibilities of infection and of the importance of observing hygienic principles when handling dogs and particularly when dealing with dejecta.

Carcinoma of Gallbladder.—The authors assess the incidence of carcinoma of the gallbladder and evaluate its relationship to gallstones. Cooke and co-workers obtained the registrar-general's figures on carcinoma of gallbladder and bile ducts in England and Wales, and for comparison they examined the necropsy records at the Postgraduate Medical School, Hammersmith, over the 10 years 1941-1950 and at the Central Middlesex Hospital over the 5 years 1947-1951. It was interesting that the proportion of all cancers of the liver and biliary passages, expressed as a percentage of all cases of cancer, was almost identical in the hospital figures and in the registrar-general's return, but there was a reversal of the ratio of carcinoma of the gallbladder to carcinoma of the bile duct. In the hospital necropsy series, bile duct carcinoma is twice as common as carcinoma of the gallbladder, whereas in the registrar-general's figures carcinoma of the bile duct is only a quarter as common as carcinoma of the gallbladder. There can be no doubt that the hospital series is the more accurate of the two. Carcinoma of the bile duct is easily confused with carcinoma of the liver, and it is likely that in the registrar-general's figures some of the bile duct cases were included under the heading of primary carcinoma of the liver. It seems clear that in Britain cancer of the gallbladder accounts for less than 1% of all deaths from cancer. Reports are cited from various countries that show that a high percentage of patients with carcinoma of the gallbladder also have gallstones, the percentages ranging from 57 to 88%. In order to assess the risk of carcinoma of the gallbladder developing in a person with a gallstone, scrutiny was made of all the necropsy records at a hospital having very detailed and accurate records. Carcinoma of the gallbladder was found at necropsy in 3% of 231 patients in whom gallstones were present. Carcinoma, however, is not the only risk associated with gallstones. In analyzing the necropsy records the opportunity was taken to record whether or not the presence of gallstones had contributed to the death of the patient—for example, by producing obstructive jaundice or empyema of the gallbladder. Studied in this way, the gallstones had exerted an appreciable effect. In 30 of the 231 patients with gallstones, 1 in 8, death was the direct consequence of the stones. Evidence is cited that indicates that it seems reasonable to reserve surgery for patients who have troublesome symptoms from their gallstones. The risk of carcinoma is not in itself sufficient reason for advocating cholecystectomy for symptomless gallstones.

Renal Factors in Hypertension.—Wilson feels that it is tempting to speculate that the kidneys and adrenals form part of a homeostatic mechanism which, through the control of tissue electrolytes, maintains arteriolar tone and adapts the blood pressure to changes in the internal environment. He discusses the role of the adrenals, assuming that some active principle resembling the salt hormone is involved. It is possible that other adrenal steroids may also play a part. Cortisone is known to produce hypertension under certain conditions. If experiments have established a reasonable presumption that renal hypertension is maintained through some action of the kidney on an adrenal cortical hormone and that this in turn acts through the influence of tissue electrolyte distribution on arteriolar tone, then the first step has been taken toward an understanding of the physiological mechanisms involved in renal hypertension. Discussing kidney lesions and hypertension, Wilson shows that the concept of the vicious circle was a natural corollary of the dual proposition that, on the one hand, renal vascular occlusion gives rise to hypertension and that, on the other, hypertension leads to occlusive vascular lesions. With regard to the application of experimental results the author deals with certain problems of high blood pressure in primary disease of the kidneys, in particular chronic nephritis and unilateral renal disease.

Orbital Leukotomy.—Tow and Lewin practiced orbital leukotomy because of the evidence that the orbital surface, rather than the superolateral surface of the lobe, is concerned with the predominantly emotional and affective aspects of behavior, and that general personality damage is roughly proportional to the amount of frontal tissue destroyed. They regarded the operation as a first step in narrowing the full leukotomy procedure. In their choice of the orbital surface, they were influenced by the work of Scoville (1948 and 1949), who introduced a technique for "undercutting" all three surfaces of the frontal lobe. The operation of orbital leukotomy consists in making a line of cleavage with a brain spatula and a fine suction-tube at the junction of the grey and white matter above the orbital grey matter on each side, extending from the frontal tips back to the level of the base of the anterior clinoid processes, with interruption of the long and short association fibers to the thalamus and to the adjacent frontal cortex. In some cases it was found necessary to sacrifice a main venous tributary running across the face of the frontal pole, but apart from this, no major vessels are divided. By operating under direct vision and with reference to definite landmarks one attempts to produce a discrete isolation of the orbital cortex without damaging the adjacent frontal cortex or its blood supply. The authors had performed between January, 1950, and December, 1951, orbital leukotomy on 20 patients without a surgical death. The only fatality in this series took place 17 months after the operation. The patients were observed throughout their entire postoperative period to date, which now extends from one and a half to three years. Seven of the patients recovered and eight others improved. Recovery or improvement takes place in the first few weeks or months. Because physical and psychological complications are minimal and beneficial effects are comparable with those of prefrontal leukotomy, orbital leukotomy is recommended for trial, particularly in patients with severe intractable tension and disturbed behavior, as an alternative to the standard operation.

Association Between Bulbar Poliomyelitis and Previous Tonsillectomy.—A survey of patients who contracted poliomyelitis during the 1947-1948 epidemic in South Australia showed that, of the 103 patients in whom the disease was associated with paralysis, 40 had bulbar paralysis. Thirty-five of the 40 had previously undergone tonsillectomy; 4 had not. For one patient this information was not obtained. Only 1 of the 35 patients had had a tonsillectomy recently; there was a 15 day interval between tonsillectomy and onset of poliomyelitis, while 16 of the remaining 34 patients had contracted the disease five or more years after the tonsillectomy. No evidence was found of an association between previous tonsillectomy and poliomyelitis other than bulbar; both nonbulbar paralytic and nonparalytic figures were tested. Comparison of age distribution of patients with bulbar and nonbulbar paralytic poliomyelitis showed that none of the 35 patients with bulbar poliomyelitis was younger than 5 years. The curve for the age distribution of the patients with bulbar poliomyelitis was much sharper than that of the patients with nonbulbar poliomyelitis associated with paralysis. Studies on the duration of the association between bulbar poliomyelitis and previous tonsillectomy revealed only short intervals since tonsillectomy in the younger age groups. The effect of the tonsillectomy, that is the strength of the association between bulbar poliomyelitis and previous tonsillectomy, was still significant in the group between 17 and 20 years, suggesting that the duration of the effect is likely to be prolonged since the modal age for tonsillectomy is five or six years. The figures were too small for definite conclusions in the group of patients with bulbar paralysis aged 21 and over. The effect of tonsillectomy lasted at least 9 or 10 years in the group between 12 and 20 years. Longer durations for the association between bulbar poliomyelitis and tonsillectomy, even possibly lifelong, are not excluded and are possible. The age distribution of the patients with bulbar paralysis but who did not have a tonsillectomy suggested that there is an increased liability to contraction of bulbar poliomyelitis with certain increases of age, independent of tonsillectomy. The association between bulbar poliomyelitis and previous tonsillectomy favors the concept that the poliomyelitis virus gains entry to the medulla via the motor pathway from the tonsillar area of the pharynx to the nucleus ambiguus. There is no evidence that the tonsils are specifically protective against this port of entry of the virus, but that the trauma of tonsillectomy renders the motor nerves of the tonsillar region more accessible to the entry of the virus to them from the pharyngeal surface. A brief survey of the patients who contracted poliomyelitis during the 1949-1950 epidemic of poliomyelitis in South Australia showed that of 19 patients with bulbar paralysis 14 had previously been tonsillectomized and 5 had not. In only 1 of the 14 patients was the tonsillectomy recent, with an 11 days interval between tonsillectomy and onset of symptoms.

Venous Pressure in Fold of Elbow: Clinical and Experimental Study. J. L. Duomarco and R. Rimini.—p. 199.
*Malignant Tumors of Hypophysis. A. Mosovich.—p. 218.
Ballistocardiographic Changes in Sarcoidosis. L. de Soldati, J. Doyle and R. Navarro Viola.—p. 228.

Malignant Tumors of Hypophysis.—There is a small group of hypophysial tumors that, unlike the benign hypophysial adenoma, invade the cranial bones, paranasal sinuses, dura mater, leptomeninges, cerebral nerves, brain stem, and cerebral tissue. The neurological symptoms correspond to the structures in which the tumor grows. They consist mainly of repeated crises of acute headache with nausea and vomiting, ocular and visual disturbances, disorders of hearing, paralysis of the cerebral nerves, trigeminal neuralgia, and, in women, amenorrhea of long duration. The diagnosis is made by roentgenography and tomography. These are likely to show an enormous enlargement and erosion of the sella turcica and the presence of a tumor in the clinoid process, the temporal and occipital bones, the paranasal sinuses, or other structures. The tumor grows slowly and does not metastasize. Roentgen therapy produces temporary improvement. Violent aggravation of the symptoms with multiple paralyses of the cerebral nerves, ocular proptosis, pain of the eyeballs, and photophobia mark the onset of the final stage that lasts a few hours. There is mental disorientation of the patient, acute general convulsions, and finally coma. The author reports two cases. The first patient, a 32-year-old man, had acromegaly for 17 years. Roentgen therapy controlled almost all of the symptoms for four years, during which the patient was able to work. The second patient, a 35-year-old woman, had neurological symptoms for four years prior to the treatment and amenorrhea for the last two years. Roentgen therapy improved moderately the symptoms for six months. The second roentgen treatment failed. In both cases the final stage lasted o two days. It was observed at necropsy that the involvem of the leptomeninges progressed to the pontocerebellar an the protuberance, and the sinus cavernosus in one case to the optic nerves, left gasserian ganglion, and paran sinuses in the other. In both cases the tumor infiltrated sphenoid and right petrous bones. The blood vessels and ne near the tumor were buried in the neoplastic tissue, their structure was well preserved. The author describes histological differences between these tumors and benign hy physial adenomas. The term malignant adenoma is m proper than hypophysial carcinoma, by which the aforem tioned tumors are commonly designated.

Radioactive Iodine in Hyperthyroidism.—The authors I^{131} to treat 18 patients with Basedow's disease and 7 Plummer's disease. They conclude that this treatment sh be limited to aged persons with hyperthyroidism, to t with recurrences after surgery or who failed to respond antithyroid drugs, those in whom hyperthyroidism is a ciated with heart disease, and those who refuse surgery. of the main problems of this treatment is the determina of a suitable dose of I^{131}. Although many methods have used to estimate the effective dose, the best is still to calcu it according to the volume of the gland and the uptake of I^{131}. The initial dose should range from 5 to 10 mc avoid severe local reactions (painful congestion of the thy and dysphagia), thyrotoxic crises, and excessive thyroid hibition resulting in hypothyroidism. Generally the good ef of radioactive iodine therapy become manifest after one two months. If the first dose proved inadequate it is safe to administer additional I^{131} up to a total dose of 20 to 25 mc. An initial dose of 15 to 25 mc. generally ca side-effects as it did in some of the authors' patients. T aggravate the thyrotoxic state and a thyrotoxic crisis foll The authors suggest treating the patients before and after administration of I^{131} with antithyroid drugs. A tracer dos I^{131} should also be given before the treatment is institu

Epidemic of Q Fever.—Numerous cases of febrile influe with or without mild complications of the respiratory a ratus were observed at Ozzano in the province of Bolo during the first six months of 1952. The clinical manifestati were atypical in six of these persons, and pulmonary t due to virus and rickettsiae were suspected. Two of these patients were members of a family of share croppers four whom had also been ill within a short time of each ot Laboratory studies to establish a definite a posteriori d nosis were made on the serum of these patients in July. Si the reaction to the complement fixation test was positive Q fever in all the patients, the serum of the other memb of the family and of other persons who had been ill dur the epidemic was also studied. The reaction was positive 8 of the 14 members of the family and one housewife amo the other persons. Attempts were not made to isolate Rickettsia burneti because of the long interval that had elap from the time of the illness. The disease had become manif with the classic picture of pneumonia in four of nine patients and with a picture of pseudoinfluenza in the other five. Penicillin and sulfonamides had no effect on the disease, and months later the agglutination titer was still elevated. The source of the infection was ascribed to a herd of sheep that ranged near the farmers' house many months of the year. The serum agglutination was positive for Q fever in 3 of the 15 sheep that were studied. The epidemic had begun at the time the births among the animals were more numerous and when the contact was more likely to occur. The members of the family had probably become infected through material contaminated with feces and urine spread in the vicinity of the house by the sheep. For the three persons who had no apparent contact with the animals the source of infection was attributed to fresh cheese they had consumed and that had been prepared from milk of these sheep.

Blood Picture in Patients with Porphyria.—The authors reviewed the cases of porphyria reported in the literature and studied in particular 53 cases in which the blood findings had been discussed. The blood picture varied during the various phases of the disease. Polyglobulism was present (11 cases) in the initial phase and severe anemia (13 cases) during the final stage of the disease when the patient's condition was precarious. The findings of blood chemistry studies were normal during the intermediate phase of the disease when the patient's general condition was not severely impaired. The passage from a state of polyglobulism to one of anemia through an intermediate state with normal blood chemistry findings has been proved by various authors with repeated blood examinations. Polyglobulism, when present, was always normochromic. Because the blood chemistry in patients with porphyria has been studied only during the late phases of the disease, polyglobulism was believed to be more uncommon than it really is. The origin of polyglobulism is ascribed to a stimulating action of the porphyrins on erythropoiesis. This action has a tendency to become attenuated and disappear during the later phases of the disease, and this explains why polyglobulism is less common during those phases. Anemia, when present, was always oligochromic. Several theories have been advanced to explain its origin in patients with porphyria. The finding of large amounts of iron in the liver and spleen of patients in whom porphyria was complicated by a severe anemia seems to confirm Vannotti's theory that it is due to inability of the red blood cells to utilize iron. Studies of the bone marrow during the period of severe anemia revealed a normoblastic erythropoiesis with a large number of erythroblasts. The number of the white blood cells was not altered during the initial phase of the disease, but there was a neutrophilic leukocytosis in the acute phase, whereas the number decreased during the late stages when severe anemia was present. Some authors have reported an increase of the number of lymphocytes over that of neutrophil granulocytes. This proved to be true only in those cases in which the marrow was severely impaired.

*Harmful Effects of Diets Deficient in Proteins. A. Arends and H. O. Nieweg.—p. 2123.
Risk of Stillbirth of Children Late in Order of Birth or Children of Mothers Advanced in Years. D. Hoogendoorn.—p. 2130.

Harmful Effects of Diets Deficient in Proteins.—Arends and Nieweg present the histories of five patients in whom various pathological conditions developed as the result of low protein diets. A woman, aged 52, had eaten a low protein diet for about 18 months because of disturbances in renal function, and for about six weeks her diet had been practically free of protein. After this megaloblastic anemia developed. Liver function tests revealed megaloblastic anemia in a 42-year-old woman whose diet over a period of six years had contained no animal proteins because she had renal disease with hypertension. An 18-year-old boy who had received a diet very low in protein because uremia was always impending, had a blood picture characteristic of erythroblastic anemia. He died and necropsy revealed severe atrophy of the spleen. The fourth patient, a 53-year-old woman, had been given a low protein diet for six months. This woman and the fifth patient, a man aged 45, showed severe liver damage at autopsy. Protein deficiency may have a harmful effect on the liver.

Burns and Their Treatment.—Schjelderup says that shock treatment of burns in adults should be started when the burned area exceeds 15% of the body surface. According to Wallace's rule of 9 for determining the amount of fluids to be given intravenously during the first 24 hours of treatment, the surface of the body is divided into areas of 9 and 18% of the whole; ½ liter colloids and ½ liter sodium chloride solution per 9% of burned surface are given intravenously, together with 2 liters of fluid orally. The estimated amount of fluid is administered in the course of the first 24 hours after the injury, half of it during the first 8 hours, reckoning the time from the moment of the injury, and the rest during the remaining 16 hours. A limit is set at 3 liters of colloids, 3 liters of electrolytes, and 2 liters of fluids orally. For the second day the quantity of fluids is cut in half. A table for computation of the amount of fluids for children is included. Hyperthermia in children is cautioned against. The Evans formula for assessment of the amount of fluids is also given. To control the effect of treatment the urinary output, hemoglobin percentage, and blood pressure must be watched carefully. All deep and extensive burns require whole blood transfusion from the start; half the estimated amount of colloids and electrolytes is replaced by whole blood. The synthetic colloids, such as dextran, Macrodex (6% solution of dextran in 0.9% isotonic sodium chloride solution), and polyvinylpyrolidone (Plasmosan), are recommended. Anemia develops during the granulation period; the only treatment is blood transfusion. The aim is to cover the open surfaces with skin grafts as soon as possible. The hemoglobin percentage must not be allowed to fall below 60, as skin grafts do not take when anemia becomes marked. Wallace's exposure treatment with early excision and grafting is recommended.

Sleep Therapy and Cure by Sleep as Psychiatric and Psychosomatic Therapeutics.—A distinction should be made between sleep therapy, which aims to set the autonomic nervous system at rest, and treatment involving the therapeutic aspects of sleep itself. In both methods a neuroplegic, chlorpromazine (10-[γ-dimethylaminopropyl]-2-chlorophenothiazine hydrochloride) is the drug of choice for bringing about prolonged sleep. Results of the use of sleep therapy have been very encouraging in cases of agitation; acute psychosis, mental confusion, and subacute delirium tremens; anxiety, depression, and melancholia; schizophrenic excitation; hallucinatory and delirious syndromes; phobic neurosis, neurasthenia, hysteria, hypochondriasis, and psychosomatic disorders; insomnia resisting other methods of treatment; and toxicomania. In all but the most acutely affected patients the state of sleep induced by chlorpromazine need not be complete, but only pharmacodynamic. The patient must be carefully watched at all times, especially during the beginning of the treatment when rather large doses of the drug are being given in order to begin the sympathicoplegia. Although treatment may have to be continued over a period of several weeks, chlorpromazine is valuable in that it abates tension within 48 hours. The authors feel that sympathicoplegic sleep therapy is more manageable and of greater scope than is cure by sleep.

*Hypophysectomy in Man. P. Détrie.—p. 1209.

Hypophysectomy in Man.—Hypophysectomy has been performed in human beings because of Cushing's syndrome that does not yield to irradiation of the pituitary region or that shows a radioresistant relapse, severe arterial hypertension, severe diabetes with retinopathy and chronic nephritis not improved by adequate doses of insulin, malignant tumors of the breast and prostate, chorioma, and malignant melanoma. The basis for this operation is the apparent correlation between certain tumors and the sex hormones. It has been demonstrated experimentally that hypophysial implants stimulate the evolution of experimental cancers, that hypophysectomy hinders their appearance, and that it stops the action of sex hormones on certain glands. Results of the operations performed so far have been most successful with Cushing's disease, the only condition in which incomplete removal of the gland is authorized, and with chorioma. The operations were followed by death in all the patients with arterial hypertension; that and endocrine disorders seem to constitute the major contraindications to hypophysectomy. Otherwise, it appears not to be a dangerous operation unless the patient is in very poor condition. The main problem from the therapeutic point of view is whether subtotal exeresis of the hypophysis is sufficient for the inhibition of cancerous growths, in view of the fact that it has regenerated in some cases, and whether total exeresis is harmful to the body as a whole, despite the powers of hormone therapy. From the surgical point of view the problem is how to achieve a total hypophysectomy, if it is necessary, without injuring any of the surrounding structures.

Studies in Gout.—The subjects of these studies were 115 gouty patients. All were given crystalline colchicine tablets to relieve symptoms of acute gout. Of 32 suffering from chronic gout, 29 were treated with sodium salicylate. In only one did the blood serum uric acid level initially fail to drop; the patient showed severe renal impairment. A second patient refused to continue treatment; but for the other 27, sodium salicylate administered continuously for periods of up to 34 months had good results. Continuous treatment was shown to be necessary by the failure of an experimental dosage of the drug—90 grains (5.82 gm.) a day for three consecutive days per week—to maintain continuously a lowered serum uric acid level. Sodium salicylate can be tolerated for prolonged periods in a dosage sufficient to maintain the serum uric acid level at a normal or nearly normal level. Tolerance to the drug usually develops within a few weeks. With reasonable control, there is little risk of hemorrhagic complications. Experiments with diets of varying purine content confirmed the belief that the serum uric acid cannot be effectively controlled by the limitation of purine intake, because the change that it does bring about is too slight. The control of serum uric acid achieved by sodium salicylate therapy produced marked alleviation of the symptoms of chronic gout in the patients treated; the destructive changes induced by urate deposition were arrested and partially repaired Twenty patients obtained complete relief from pains in the joints.

Multiple Malignant Neoplasms.—Instances of tumor presenting all or the first two of Billroth's postulates should be reported. According to these postulates, the tumors should have different histological characteristics, should have their origin in different organs, should follow an independent course, and should give rise to metastases according to their proper type. The last postulate may be lacking because metastases are not always present. The authors' patient, a woman 50 years old, had an osteosarcoma removed from the upper third of the left radius at the age of 32, an adenocarcinoma removed from the left breast at the age of 44, and a myosarcoma removed from the left thigh at the age of 49. The patient's father died from gastric cancer. Two brothers died from sarcoma of the thigh and adenoma of the breast, respectively. The remaining four brothers are normal. Multiple cancer, as the cause of death, is extremely rare. If it is identified early, prompt surgical treatment is efficacious.

Penicillin Therapy of Epidemic Meningitis.—The author discusses serum therapy, sulfonamides, and antibiotics in the treatment of epidemic meningitis, and he asserts that the best therapy is parenteral administration of penicillin in adequate doses. Five of his patients recovered completely after administration of that antibiotic. Three of them were given 1,000,000 I. U. of the antibiotic at admission and 500,000 units every three hours thereafter. The temperature returned to normal after 10, 8, and 12 days respectively. Aspecific meningitis, which was ascribed to excess doses of penicillin, developed in two who recovered after administration of the antibiotic was discontinued. The other two patients were given 1,000,000 units of penicillin at admission and 1,500,000 units of penicillin for prolonged action after three hours. This dose was repeated every 24 hours thereafter. On the fourth day the temperature was normal in one patient who recovered completely. A swelling had appeared on the left knee of the other patient suggesting that the meningococci had become localized in the knee. About 50 cc. of fluid containing polynuclear leukocytes and meningococci were removed, and 1,000,000 units of penicillin were introduced. The patient made a full recovery. There were no sequelae in any of the patients.

*Study of Postpartum Hemorrhages Due to Afibrinogenemia: Fibrinolytic and Anticoagulant Action of Amniotic Fluid in Cases of Fetal Maceration. G. Vecchietti.—p. 443.
In Situ Cancer of Neck of Uterus. W. Ingiulla and E. Ogier.—p. 453.

Postpartum Hemorrhages Caused by Decrease or Absence of Fibrinogen.—Postpartum hemorrhages resulting from hypofibrinogenemia or afibrinogenemia occur frequently in women with anti-Rh isoimmunization and dead fetuses in utero and, independently from a state of isoimmunization, in women whose fetuses have undergone maceration. Several hypotheses have been advanced to explain the pathogenesis of this condition. Toxic effects of placental and fetal substances may interfere with the liver production of fibrinogen; substances of placental and amniotic origin with a thromboplastinic activity may enter the maternal circulation and cause defibrination of the plasma; or fibrinolytic enzymes originating from the decidua and the placenta may enter the maternal blood stream. These hemorrhages may also be the expression of an exaggerated fibrinolytic defense process following the penetration of thromboplastin into the maternal circulation. Previous studies have indicated that the amniotic fluid has an anticoagulant and fibrinolytic activity. Some authors are of the opinion that the fluid may enter the maternal circulation and cause pronounced blood coagulation defects and not acute embolism. The author studied the amniotic fluid of a woman in the eighth month of pregnancy whose fetus had been dead in utero one month. He removed transabdominally 50 cc. of turbid, reddish amniotic fluid, and four hours later a macerated fetus weighing 690 gm. was delivered. He removed about 18 cc. of cerebrospinal fluid from the third ventricle of the fetus and then studied the effect of the two fluids on the process of blood coagulation. There was a fibrinolytic and a definite heparin-like anticoagulant activity in both. In comparative studies with heparin, the anticoagulant activity of the fluids proved to be equal to that of a fluid containing from 5,000 to 10,000 I. U. of heparin. The amniotic fluid had a greater fibrinolytic activity, the cerebrospinal fluid a greater anticoagulant activity. Thus amniotic fluid penetrating into the maternal circulation may also be responsible for the postpartum hemorrhages that occur in women with anti-Rh isoimmunization with dead fetuses in utero and in those whose fetuses have undergone maceration.

*Estimation of Portal Venous Pressure by Occlusive Hepatic Vein Catheterization. H. Krook.—p. 285.

Estimation of Portal Venous Pressure by Occlusive Catheterization of a Hepatic Vein.—A new method recently described by Myers and Taylor for measuring portal venous pressure by occlusive catheterization of a hepatic vein was tried on 10 persons without any symptoms or signs of hepatic disease, on 14 patients with chronic disease of the liver 10 of whom had liver cirrhosis and portal hypertension syndrome, and on 5 patients with congestive heart failure. The pressure recorded from the occluded hepatic vein in those without apparent liver disease ranged from 3 mm. Hg to 10 mm. Hg (average 6.4 mm. Hg). The pressure recorded from the occluded hepatic vein was increased in patients with cirrhosis, the increase usually varying with the severity of the clinical symptoms of hypertension. The pressure recorded in the 10 patients with portal hypertension syndrome varied from 12 mm. Hg to 27 mm. Hg (average 21 mm. Hg). The level of the pressure recorded in the five patients with congestive heart failure, three of whom had constrictive pericarditis, was about the same as that of the systemic vein pressure, i. e., 11 mm. Hg to 20 mm. Hg (average 15 mm. Hg). The pressure recorded from a central, unoccluded hepatic vein was low in both apparently healthy persons and patients with cirrhosis, the averages being 4 mm. Hg and 4.8 mm. Hg, respectively. There is much to suggest that the pressure measured with the aid of a catheter occluding a small peripheral branch of the hepatic vein represents the pressure in the portal vein and that the method is useful for assessing the degree of portal hypertension.

Sleep Therapy and Cure by Sleep as Psychiatric and Psychosomatic Therapeutics.—A distinction should be made between sleep therapy, which aims to set the autonomic nervous system at rest, and treatment involving the therapeutic aspects of sleep itself. In both methods a neuroplegic, chlorpromazine (10-[γ-dimethylaminopropyl]-2-chlorophenothiazine hydrochloride) is the drug of choice for bringing about prolonged sleep. Results of the use of sleep therapy have been very encouraging in cases of agitation; acute psychosis, mental confusion, and subacute delirium tremens; anxiety, depression, and melancholia; schizophrenic excitation; hallucinatory and delirious syndromes; phobic neurosis, neurasthenia, hysteria, hypochondriasis, and psychosomatic disorders, insomnia resisting other methods of treatment; and toxicomania. In all but the most acutely affected patients the state of sleep induced by chlorpromazine need not be complete, but only pharmacodynamic. The patient must be carefully watched at all times, especially during the beginning of the treatment when rather large doses of the drug are being given in order to begin the sympathicoplegia. Although treatment may have to be continued over a period of several weeks, chlorpromazine is valuable in that it abates tension within 48 hours. The authors feel that sympathicoplegic sleep therapy is more manageable and of greater scope than is cure by sleep.

*Hypophysectomy in Man. P. Détrie.—p. 1209.

Hypophysectomy in Man.—Hypophysectomy has been performed in human beings because of Cushing's syndrome that does not yield to irradiation of the pituitary region or that shows a radioresistant relapse, severe arterial hypertension, severe diabetes with retinopathy and chronic nephritis not improved by adequate doses of insulin, malignant tumors of the breast and prostate, chorioma, and malignant melanoma. The basis for this operation is the apparent correlation between certain tumors and the sex hormones. It has been demonstrated experimentally that hypophysial implants stimulate the evolution of experimental cancers, that hypophysectomy hinders their appearance, and that it stops the action of sex hormones on certain glands. Results of the operations performed so far have been most successful with Cushing's disease, the only condition in which incomplete removal of the gland is authorized, and with chorioma. The operations were followed by death in all the patients with arterial hypertension; that and endocrine disorders seem to constitute the major contraindications to hypophysectomy. Otherwise, it appears not to be a dangerous operation unless the patient is in very poor condition. The main problem from the therapeutic point of view is whether subtotal exeresis of the hypophysis is sufficient for the inhibition of cancerous growths, in view of the fact that it has regenerated in some cases, and whether total exeresis is harmful to the body as a whole, despite the powers of hormone therapy. From the surgical point of view the problem is how to achieve a total hypophysectomy, if it is necessary, without injuring any of the surrounding structures.

Studies in Gout.—The subjects of these studies were 11 gouty patients. All were given crystalline colchicine tablet to relieve symptoms of acute gout. Of 32 suffering fron chronic gout, 29 were treated with sodium salicylate In onl one did the blood serum uric acid level initially fail to drop the patient showed severe renal impairment. A second patien refused to continue treatment; but for the other 27, sodiur salicylate administered continuously for periods of up to 3 months had good results. Continuous treatment was show to be necessary by the failure of an experimental dosage o the drug—90 grains (5.82 gm.) a day for three consecutiv days per week—to maintain continuously a lowered serur uric acid level. Sodium salicylate can be tolerated for prolonged periods in a dosage sufficient to maintain the serur uric acid level at a normal or nearly normal level. Toleranc to the drug usually develops within a few weeks. With reasonable control, there is little risk of hemorrhagic complications. Experiments with diets of varying purine content confirmed the belief that the serum uric acid cannot be effectivel controlled by the limitation of purine intake, because th change that it does bring about is too slight. The control o serum uric acid achieved by sodium salicylate therapy produced marked alleviation of the symptoms of chronic gou in the patients treated; the destructive changes induced b urate deposition were arrested and partially repaired Twent patients obtained complete relief from pains in the joints.

Multiple Malignant Neoplasms.—Instances of tumor presentin all or the first two of Billroth's postulates should be reported According to these postulates, the tumors should have differen histological characteristics, should have their origin in differen organs, should follow an independent course, and should give rise to metastases according to their proper type. The las postulate may be lacking because metastases are not alway present. The authors' patient, a woman 50 years old, had ar osteosarcoma removed from the upper third of the left radiu at the age of 32, an adenocarcinoma removed from the left breast at the age of 44, and a myosarcoma removed from the left thigh at the age of 49. The patient's father died from gastric cancer. Two brothers died from sarcoma of the thigh and adenoma of the breast, respectively. The remaining four brothers are normal. Multiple cancer, as the cause of death, is extremely rare. If it is identified early, prompt surgical treatment is efficacious.

Penicillin Therapy of Epidemic Meningitis.—The author discusses serum therapy, sulfonamides, and antibiotics in the treatment of epidemic meningitis, and he asserts that the best therapy is parenteral administration of penicillin in adequate doses. Five of his patients recovered completely after administration of that antibiotic. Three of them were given 1,000,000 I. U. of the antibiotic at admission and 500,000 units every three hours thereafter. The temperature returned to normal after 10, 8, and 12 days respectively. Aspecific meningitis, which was ascribed to excess doses of penicillin, developed in two who recovered after administration of the antibiotic was discontinued. The other two patients were given 1,000,000 units of penicillin at admission and 1,500,000 units of penicillin for prolonged action after three hours. This dose was repeated every 24 hours thereafter. On the fourth day the temperature was normal in one patient who recovered completely. A swelling had appeared on the left knee of the other patient suggesting that the meningococci had become localized in the knee. About 50 cc. of fluid containing polynuclear leukocytes and meningococci were removed, and 1,000,000 units of penicillin were introduced. The patient made a full recovery. There were no sequelae in any of the patients.

- In Situ Cancer of Neck of Uterus. W. Ingiulla and E. Ogier.—p. 453.

Postpartum Hemorrhages Caused by Decrease or Absence of Fibrinogen.—Postpartum hemorrhages resulting from hypofibrinogenemia or afibrinogenemia occur frequently in women with anti-Rh isoimmunization and dead fetuses in utero and, independently from a state of isoimmunization, in women whose fetuses have undergone maceration. Several hypotheses have been advanced to explain the pathogenesis of this condition. Toxic effects of placental and fetal substances may interfere with the liver production of fibrinogen; substances of placental and amniotic origin with a thromboplastinic activity may enter the maternal circulation and cause defibrination of the plasma; or fibrinolytic enzymes originating from the decidua and the placenta may enter the maternal blood stream. These hemorrhages may also be the expression of an exaggerated fibrinolytic defense process following the penetration of thromboplastin into the maternal circulation. Previous studies have indicated that the amniotic fluid has an anticoagulant and fibrinolytic activity. Some authors are of the opinion that the fluid may enter the maternal circulation and cause pronounced blood coagulation defects and not acute embolism. The author studied the amniotic fluid of a woman in the eighth month of pregnancy whose fetus had been dead in utero one month. He removed transabdominally 50 cc. of turbid, reddish amniotic fluid, and four hours later a macerated fetus weighing 690 gm. was delivered. He removed about 18 cc. of cerebrospinal fluid from the third ventricle of the fetus and then studied the effect of the two fluids on the process of blood coagulation. There was a fibrinolytic and a definite heparin-like anticoagulant activity in both. In comparative studies with heparin, the anticoagulant activity of the fluids proved to be equal to that of a fluid containing from 5,000 to 10,000 I. U. of heparin. The amniotic fluid had a greater fibrinolytic activity, the cerebrospinal fluid a greater anticoagulant activity. Thus amniotic fluid penetrating into the maternal circulation may also be responsible for the postpartum hemorrhages that occur in women with anti-Rh isoimmunization with dead fetuses in utero and in those whose fetuses have undergone maceration.

Estimation of Portal Venous Pressure by Occlusive Catheterization of a Hepatic Vein.—A new method recently described by Myers and Taylor for measuring portal venous pressure by occlusive catheterization of a hepatic vein was tried on 10 persons without any symptoms or signs of hepatic disease, on 14 patients with chronic disease of the liver 10 of whom had liver cirrhosis and portal hypertension syndrome, and on 5 patients with congestive heart failure. The pressure recorded from the occluded hepatic vein in those without apparent liver disease ranged from 3 mm. Hg to 10 mm. Hg (average 6.4 mm. Hg). The pressure recorded from the occluded hepatic vein was increased in patients with cirrhosis, the increase usually varying with the severity of the clinical symptoms of hypertension. The pressure recorded in the 10 patients with portal hypertension syndrome varied from 12 mm. Hg to 27 mm. Hg (average 21 mm. Hg). The level of the pressure recorded in the five patients with congestive heart failure, three of whom had constrictive pericarditis, was about the same as that of the systemic vein pressure, i. e., 11 mm. Hg to 20 mm. Hg (average 15 mm. Hg). The pressure recorded from a central, unoccluded hepatic vein was low in both apparently healthy persons and patients with cirrhosis, the averages being 4 mm. Hg and 4.8 mm. Hg, respectively. There is much to suggest that the pressure measured with the aid of a catheter occluding a small peripheral branch of the hepatic vein represents the pressure in the portal vein and that the method is useful for assessing the degree of portal hypertension.

- Mechanism of Tumor Formation. A. Graffi.—p. 865.

Morphology and Pathogenesis of Coronary Occlusion.—Macroscopic and microscopic studies made of the coronary arteries of 126 patients who died of coronary occlusion revealed that the occlusion was caused by intramural hematoma associated with coronary sclerosis in 14 (8 men and 6 women between the ages of 47 and 76 years), 11.1%; by intramural hematoma with secondary thrombosis associated with coronary sclerosis in 21 (14 male and 7 female patients between the ages of 12 and 84 years), 16.7%; by simple coronary sclerosis in 30 (21 men and 9 women between the ages of 40 and 79 years), 24%; by coronary thrombosis associated with simple coronary sclerosis in 50 (44 men and 6 women between the ages of 38 and 89 years), 39.5%; and by coronaritis in 11 (8 men and 3 women between the ages of 40 and 73 years), 8.7%. The great significance of coronary arteriosclerosis in coronary occlusion was thus demonstrated. Generalized arteriosclerosis, which was observed in some of the patients of each of the five groups, also played an essential part in the causation of coronary occlusion, while intramural hematoma associated or not with thrombosis, thrombosis associated with stenotic coronary sclerosis, and coronaritis were the contributing factors. The left descending branch was the preferred site of the occlusion, while the left circumflex branch was not involved. The results of the authors' studies, particularly the demonstration of coronary thromboses in nearly two thirds of the cases, are of considerable interest with respect to treatment of cardiac infarction with anticoagulants. Anticoagulants may not only prevent the formation of parietal thromboses but also have an effect on the coronary arteries by preventing the appositional growth of the coronary thrombi in the proximal direction. The advantages of the anticoagulant therapy may, therefore, overbalance the occasional disadvantages of a possible increase of intramural hemorrhages.

Action of Methyl Androstenediol on Growth in Children.—Methyl androstenediol (17α-methyl-Δ^5-androstene-3β, 17β-diol, steroid) is a hormone that when given in therapeutic doses has very weak androgenic properties and a strong stimulating effect on protein anabolism, thereby rendering it particularly suitable for treatment of simple retarded growth in children without accompanying sexual deficiencies. Results of the administration of dipropionate methyl androstenediol to 13 patients (8 boys and 5 girls) of from 6 to 17 years of age and of dipropionate androstenediol to one 22-year-old woman showed positive evidence of statural growth in 6, slight evidence in 4, and no evidence in 4. There was no premature fusion of the epiphyses. Ponderal growth occurred in five. Tolerance of the medicament was good in all patients; there was improvement of the psychic state in four; and appetite increased in two. The authors conclude that the stimulating effect on bone growth of the products used is undeniable, at least on a short-term basis, but that it is impossible to judge whether the final height is influenced by these hormones.

Indications for and Results of Portacaval Shunts in Cirrhosis of Liver. A. Vachon and A. Grivet.—p. 2790.

Portal Obstruction.—Banti's description in 1894 of a disease of the spleen characterized by fibroadenomatous splenomegaly has given rise to the incorrect grouping in a single syndrome of a number of different diseases manifested in this manner. Obstruction of the portal system constitutes one of the major diseases wrongly classified in this way. Of the 63 patients operated on by the author or a colleague for "Banti's syndrome" since 1948, 40 had portal obstruction and 23 portal hypertension, of which 4 cases were metaicteric and 19 of the type of Banti. Congenital stenosis of the portal vein is frequent in children, but its manifestations are often delayed until the 10th or 15th year. Inflammatory stenosis, such as that following appendectomy, and thrombosis of the portal vein are found in adults. Contrary to the belief of Whipple, Blakemore, and others that only intrahepatic block causes cirrhosis of the liver, the author finds that cirrhosis may be associated with these extrahepatic obstructions when compensatory portahepatic anastomoses are scarce and weak. The clinical manifestations of portal obstruction are hemorrhages due to the rupture of cardioesophageal varices, followed by painful hypersplenia and, very occasionally, ascites. Obstructions localized at the splenic vein are treated by simple splenectomy. Portal stenosis with residual hypertension after splenectomy requires an anastomosis of the splenic and renal veins. This operation has a very small percentage of relapses after three years. Splenectomy is not indicated for an obstruction of the portal vein because, if a relapse should occur, a splenorenal anastomosis is impossible and an anastomosis, whether direct or by graft, of the superior mesenteric vein and the vena cava is not always possible. Radiographic and manometric checking of the portal system should be practiced systematically during surgery for hemorrhages of splenic origin and before splenectomy whenever diagnosis of splenopathy is in doubt.

*Experimental Studies on Fibrinolytic, Embololytic and Anticoagulant Effect of Intravenous Administration of Pancreatic Enzymes with Particular Reference to Lysis of Emboli in Pulmonary Arteries. F. Zini.—p. 304.
*Use of Hyaluronidase in Renal Lithiasis: Synthetic Critical Review. F. Tinacci.—p. 312.

"Fibrinoclasi" on Emboli of Pulmonary Arteries.—"Fibrinoclasi" is a mixture of two pancreatic enzymes with a pronounced fibrinolytic and anticoagulant activity. In the author's experiments intravenous administration of the preparation caused lysis of the emboli that were localized in the pulmonary arteries of rabbits. He produced the emboli by injecting clots of blood that had been removed from the animal's heart into the marginal vein of its ear. Then he injected the fibrinolytic preparation diluted in isotonic sodium chloride solution very slowly into the same vein or into the heart. Doses of 20, 40, and 100 mg. were used. The coagulation time was prolonged and the plasma fibrinogen level was decreased 4 to 16 hours after the injection. The prothrombin time was markedly prolonged and the plasma accelerating factor was scarce. The fibrinolytic properties of the plasma were increased. After 24 hours there was a return to the initial values. Macroscopic and microscopic studies were made of the pulmonary arteries of the rabbits that had received 100 mg. of the preparation. Although there were no emboliform intravasal formations, there was evidence that the vessels had been impaired and that a phase of resumed function was following a state of particular nonspecific physiopathological impairment. But to obtain the lysis of the emboli, the preparation should be administered as soon as possible after the clots have formed. The preparation is much more effective on clots of recent formation. Because of its effects, the action of "Fibrinoclasi" resembles that of heparin more than that of bishydroxycoumarin (Dicumarol).

Hyaluronidase in Renal Lithiasis.—Administration of hyaluronidase is a new method for treating and preventing renal lithiasis. Its use is based on the concept that the colloids present in the urine prevent the precipitation of urinary crystalloids and a decreased concentration of urinary colloids is responsible for a greater tendency of the urinary crystalloids to precipitate and cause stone formation. Since it was found that the urinary colloidal activity is more pronounced in persons with a normal urinary apparatus than in patients with renal lithiasis, injections of hyaluronidase were made to increase the concentration of the colloids in the urine and thus prevent or arrest the formation of stones. The action of hyaluronidase in patients with renal lithiasis is indirect. Hyaluronic acid is released at the site of the injection; the connective barrier begins to reconstitute itself while the hyaluronidase action is dissipated. During this phase excess hyaluronic acid or a similar substrate passes into the blood, is excreted in the urine, and thus acts as a protective colloid. The author believes that to be effective the treatment should be continued indefinitely because of the transitory action of the enzyme. But, since a prolonged administration of hyaluronidase may cause side-effects or produce an increased serum concentration of antihyaluronidase that would render useless the injected enzyme, he suggests the use of hyaluronic acid or chondroitin sulfuric acid. These have the same effect on the urine colloidal activity as subcutaneous injections of hyaluronidase, but, since they do not have an antigen power nor the characteristics of haptens, their parenteral or intravenous administration could be continued indefinitely without harm to the organism.

*Effect of Thyroid Extract in Hypertension. B. A. Bradlow, M. McGregor, M. M. Zion and T. H. Bothwell.—p. 717.

Thyroid Extract in Hypertension.—Bradlow and associates attempted to reproduce the encouraging results that Menof obtained with thyroid extract in many hypertensive subjects. They gave thyroid extract to 22 patients with hypertension after a control period of placebo administration. Two out of 18 patients had a decrease in diastolic pressure of more than 15 mm. Hg on no treatment or on placebo therapy, while in 2 out of 25 trials there was a decrease in diastolic pressure of more than 15 mm. Hg during thyroid therapy. It does not appear, therefore, that thyroid extract in the dose used has any dramatic effect, beneficial or otherwise, on the level of blood pressure or on the symptoms of essential hypertension.

Penicillin and Sulfadiazine in Pneumonia.—Two hundred Bantu patients with pneumonia were divided into three groups. Uniformity was maintained with regard to sex, age, duration of illness before admission, temperature at beginning of treatment, and anatomic distribution of lesions. Those of the first group were treated with penicillin, those of the second with sulfadiazine, and those of the third with both. The evidence gained by tabulating the mean duration of pyrexia in the three groups indicates that penicillin and sulfadiazine are probably equally effective in the treatment of pneumonia and that there is nothing to be gained by administering both simultaneously. In fact, the figures, so far as they go, indicate that this practice may even be harmful. The well-known additive effect of penicillin and sulfadiazine in vitro is not reflected in the results obtained in the present study. In the group treated with penicillin, delayed resolution of the disease showed a relation to the insensitivity in vitro of the causative bacteria to the treatment prescribed. This relationship was seen to a lesser extent in the other two groups. The majority of cases with resistant bacteria in the sulfadiazine group resolved rapidly, however; this phenomenon was not seen in the other groups. It appears that sensitivity tests in vitro are of little value in predicting the outcome of any particular case when sulfadiazine is employed, but may be of value in cases treated with penicillin. All things considered, the results of treatment with penicillin appear to be slightly superior to those obtained with the other two methods.

Development of Resistance to Isoniazid.—Berg and co-workers investigated the reduction in the sensitivity of tubercle bacilli to isoniazid (isonicotinic acid hydrazid). The development of resistance during the first three months of isoniazid treatment could be ascertained on 119 patients; the dependence of the appearance of resistant strains on the form of tuberculosis could be studied on 183 patients; and for ascertaining the effect of a six month course of isoniazid therapy, 80 patients were available. It was observed that bacteriological resistance against isoniazid develops rather rapidly during the first three months of therapy; it increases moderately during the second three months. It develops with greater rapidity and greater frequency in patients with chronic tuberculosis who have larger pulmonary cavities than in patients with new exudative forms of tuberculosis. There is a close statistical relationship between reduction in sensitivity of the tubercle bacilli and the failure of therapy. If treatment is continued beyond the first three months, however, it does not necessarily follow that the presence of strains that are still sensitive implies a favorable prognosis for the carrier nor does presence of resistant strains necessarily imply an unfavorable prognosis. After the patient has been treated with isoniazid for three months without much success, the clinician should ask himself whether it would not be advisable to resort to collapse therapy. If bacterial resistance remains constant, it is advisable either to change to another chemotherapeutic substance or to try a combination of chemotherapeutic and antibiotic drugs. It should be remembered that the main effect of treatment with isoniazid is obtained during the first three months, and, if it has not materialized then, it can hardly be expected later on.

Case of Air Embolism Treated with Procaine Intravenously. K. M. Jensen.—p. 1159.

Treatment of Acquired Hemolytic Anemia with Corticotropin and Cortisone.—Four patients with immunohemolytic anemia were treated with corticotropin and cortisone with good results. In the first two patients symptoms returned after a short course of treatment, but remission was maintained for seven and six months, respectively, by the administration of 50 mg. of cortisone daily, and three months after treatment ended there had been no recurrence. In the other two patients recovery seemed to occur after a short course of corticotropin and cortisone treatment. Letman states that these cases together with 24 from the literature bring to 28 the number of cases published in which immunohemolytic anemia has been treated with corticotropin and cortisone, with satisfactory immediate results in 25. Most cases seem to recur after a short course of treatment, but with long-continued cortisone treatment in moderate doses the remission can probably be maintained in many cases. If not, splenectomy must be done, but not until the patient has been brought into a satisfactory condition with corticotropin or cortisone. Parallel with the treatment and improvement in the hemolytic anemia there was a reduction in autoimmunization and in osmotic fragility.

*Leiodystonic Syndrome in Indigenous Disease. P. H. Pock-Steen.—p. 1216.

Leiodystonic Syndrome in Indigenous Diseases.—In different chronic disorders, mainly enterogenic toxemia, a symptom complex has been manifested that Pock-Steen designates as the leiodystonic syndrome. It corresponds in all details but in different intensity to the tropical disease dystonia. Four typical cases are described, in which treatment with moderate doses of corticotropin (ACTH) gave good results. All in all, a score of such cases have been observed. The syndrome appears as a nosographic entity and includes neurocirculatory, gastrointestinal, and psychasthenic phenomena. It is the clinical expression of glucocorticoid deficiency and differs from Addison's occlusion was thus demonstrated. Generalized arteriosclerosis, which was observed in some of the patients of each of the five groups, also played an essential part in the causation of coronary occlusion, while intramural hematoma associated or not with thrombosis, thrombosis associated with stenotic coronary sclerosis, and coronaritis were the contributing factors. The left descending branch was the preferred site of the occlusion, while the left circumflex branch was not involved. The results of the authors' studies, particularly the demonstration of coronary thromboses in nearly two thirds of the cases, are of considerable interest with respect to treatment of cardiac infarction with anticoagulants. Anticoagulants may not only prevent the formation of parietal thromboses but also have an effect on the coronary arteries by preventing the appositional growth of the coronary thrombi in the proximal direction. The advantages of the anticoagulant therapy may, therefore, overbalance the occasional disadvantages of a possible increase of intramural hemorrhages.

Gastric Tumors Invaginated into the Duodenum. C. Debray and Y. Muffang.—p. 2713.

Action of Methyl Androstenediol on Growth in Children.—Methyl androstenediol (17 α-methyl-Δ^5-androstene-3 β, 17 β-diol, steroid) is a hormone that when given in therapeutic doses has very weak androgenic properties and a strong stimulating effect on protein anabolism, thereby rendering it particularly suitable for treatment of simple retarded growth in children without accompanying sexual deficiencies. Results of the administration of dipropionate methyl androstenediol to 13 patients (8 boys and 5 girls) of from 6 to 17 years of age and of dipropionate androstenediol to one 22-year-old woman showed positive evidence of statural growth in 6, slight evidence in 4, and no evidence in 4. There was no premature fusion of the epiphyses. Ponderal growth occurred in five. Tolerance of the medicament was good in all patients; there was improvement of the psychic state in four; and appetite increased in two. The authors conclude that the stimulating effect on bone growth of the products used is undeniable, at least on a short-term basis, but that it is impossible to judge whether the final height is influenced by these hormones.

Indications for and Results of Portacaval Shunts in Cirrhosis of Liver. A. Vachon and A. Grivet.—p. 2790.

Portal Obstruction.—Banti's description in 1894 of a disease of the spleen characterized by fibroadenomatous splenomegaly has given rise to the incorrect grouping in a single syndrome of a number of different diseases manifested in this manner. Obstruction of the portal system constitutes one of the major diseases wrongly classified in this way. Of the 63 patients operated on by the author or a colleague for "Banti's syndrome" since 1948, 40 had portal obstruction and 23 portal hypertension, of which 4 cases were metaicteric and 19 of the type of Banti. Congenital stenosis of the portal vein is frequent in children, but its manifestations are often delayed until the 10th or 15th year. Inflammatory stenosis, such as that following appendectomy, and thrombosis of the portal vein are found in adults. Contrary to the belief of Whipple, Blakemore, and others that only intrahepatic block causes cirrhosis of the liver, the author finds that cirrhosis may be associated with these extrahepatic obstructions when compensatory portahepatic anastomoses are scarce and weak. The clinical manifestations of portal obstruction are hemorrhages due to the rupture of cardioesophageal varices, followed by painful hypersplenia and, very occasionally, ascites. Obstructions localized at the splenic vein are treated by simple splenectomy. Portal stenosis with residual hypertension after splenectomy requires an anastomosis of the splenic and renal veins. This operation has a very small percentage of relapses after three years. Splenectomy is not indicated for an obstruction of the portal vein because, if a relapse should occur, a splenorenal anastomosis is impossible and an anastomosis, whether direct or by graft, of the superior mesenteric vein and the vena cava is not always possible. Radiographic and manometric checking of the portal system should be practiced systematically during surgery for hemorrhages of splenic origin and before splenectomy whenever diagnosis of splenopathy is in doubt.

*Experimental Studies on Fibrinolytic, Embololytic and Anticoagulant Effect of Intravenous Administration of Pancreatic Enzymes with Particular Reference to Lysis of Emboli in Pulmonary Arteries. F. Zini.—p. 304.
*Use of Hyaluronidase in Renal Lithiasis: Synthetic Critical Review. F. Tinacci.—p. 312.

"Fibrinoclasi" on Emboli of Pulmonary Arteries.—"Fibrinoclasi" is a mixture of two pancreatic enzymes with a pronounced fibrinolytic and anticoagulant activity. In the author's experiments intravenous administration of the preparation caused lysis of the emboli that were localized in the pulmonary arteries of rabbits. He produced the emboli by injecting clots of blood that had been removed from the animal's heart into the marginal vein of its ear. Then he injected the fibrinolytic preparation diluted in isotonic sodium chloride solution very slowly into the same vein or into the heart. Doses of 20, 40, and 100 mg. were used. The coagulation time was prolonged and the plasma fibrinogen level was decreased 4 to 16 hours after the injection. The prothrombin time was markedly prolonged and the plasma accelerating factor was scarce. The fibrinolytic properties of the plasma were increased. After 24 hours there was a return to the initial values. Macroscopic and microscopic studies were made of the pulmonary arteries of the rabbits that had received 100 mg. of the preparation. Although there were no emboliform intravasal formations, there was evidence that the vessels had been impaired and that a phase of resumed function was following a state of particular nonspecific physiopathological impairment. But to obtain the lysis of the emboli, the preparation should be administered as soon as possible after the clots have formed. The preparation is much more effective on clots of recent formation. Because of its effects, the action of "Fibrinoclasi" resembles that of heparin more than that of bishydroxycoumarin (Dicumarol).

Hyaluronidase in Renal Lithiasis.—Administration of hyaluronidase is a new method for treating and preventing renal lithiasis. Its use is based on the concept that the colloids present in the urine prevent the precipitation of urinary crystalloids and a decreased concentration of urinary colloids is responsible for a greater tendency of the urinary crystalloids to precipitate and cause stone formation. Since it was found that the urinary colloidal activity is more pronounced in persons with a normal urinary apparatus than in patients with renal lithiasis, injections of hyaluronidase were made to increase the concentration of the colloids in the urine and thus prevent or arrest the formation of stones. The action of hyaluronidase in patients with renal lithiasis is indirect. Hyaluronic acid is released at the site of the injection; the connective barrier begins to reconstitute itself while the hyaluronidase action is dissipated. During this phase excess hyaluronic acid or a similar substrate passes into the blood, is excreted in the urine, and thus acts as a protective colloid. The author believes that to be effective the treatment should be continued indefinitely because of the transitory action of the enzyme. But, since a prolonged administration of hyaluronidase may cause side-effects or produce an increased serum concentration of antihyaluronidase that would render useless the injected enzyme, he suggests the use of hyaluronic acid or chondroitin sulfuric acid. These have the same effect on the urine colloidal activity as subcutaneous injections of hyaluronidase, but, since they do not have an antigen power nor the characteristics of haptens, their parenteral or intravenous administration could be continued indefinitely without harm to the organism.

*Effect of Thyroid Extract in Hypertension. B. A. Bradlow, M. McGregor, M. M. Zion and T. H. Bothwell.—p. 717.

Thyroid Extract in Hypertension.—Bradlow and associates attempted to reproduce the encouraging results that Menof obtained with thyroid extract in many hypertensive subjects. They gave thyroid extract to 22 patients with hypertension after a control period of placebo administration. Two out of 18 patients had a decrease in diastolic pressure of more than 15 mm. Hg on no treatment or on placebo therapy, while in 2 out of 25 trials there was a decrease in diastolic pressure of more than 15 mm. Hg during thyroid therapy. It does not appear, therefore, that thyroid extract in the dose used has any dramatic effect, beneficial or otherwise, on the level of blood pressure or on the symptoms of essential hypertension.

Penicillin and Sulfadiazine in Pneumonia.—Two hundred Bantu patients with pneumonia were divided into three groups. Uniformity was maintained with regard to sex, age, duration of illness before admission, temperature at beginning of treatment, and anatomic distribution of lesions. Those of the first group were treated with penicillin, those of the second with sulfadiazine, and those of the third with both. The evidence gained by tabulating the mean duration of pyrexia in the three groups indicates that penicillin and sulfadiazine are probably equally effective in the treatment of pneumonia and that there is nothing to be gained by administering both simultaneously. In fact, the figures, so far as they go, indicate that this practice may even be harmful. The well-known additive effect of penicillin and sulfadiazine in vitro is not reflected in the results obtained in the present study. In the group treated with penicillin, delayed resolution of the disease showed a relation to the insensitivity in vitro of the causative bacteria to the treatment prescribed. This relationship was seen to a lesser extent in the other two groups. The majority of cases with resistant bacteria in the sulfadiazine group resolved rapidly, however; this phenomenon was not seen in the other groups. It appears that sensitivity tests in vitro are of little value in predicting the outcome of any particular case when sulfadiazine is employed, but may be of value in cases treated with penicillin. All things considered, the results of treatment with penicillin appear to be slightly superior to those obtained with the other two methods.

Development of Resistance to Isoniazid.—Berg and co-workers investigated the reduction in the sensitivity of tubercle bacilli to isoniazid (isonicotinic acid hydrazid). The development of resistance during the first three months of isoniazid treatment could be ascertained on 119 patients; the dependence of the appearance of resistant strains on the form of tuberculosis could be studied on 183 patients; and for ascertaining the effect of a six month course of isoniazid therapy, 80 patients were available. It was observed that bacteriological resistance against isoniazid develops rather rapidly during the first three months of therapy; it increases moderately during the second three months. It develops with greater rapidity and greater frequency in patients with chronic tuberculosis who have larger pulmonary cavities than in patients with new exudative forms of tuberculosis. There is a close statistical relationship between reduction in sensitivity of the tubercle bacilli and the failure of therapy. If treatment is continued beyond the first three months, however, it does not necessarily follow that the presence of strains that are still sensitive implies a favorable prognosis for the carrier nor does presence of resistant strains necessarily imply an unfavorable prognosis. After the patient has been treated with isoniazid for three months without much success, the clinician should ask himself whether it would not be advisable to resort to collapse therapy. If bacterial resistance remains constant, it is advisable either to change to another chemotherapeutic substance or to try a combination of chemotherapeutic and antibiotic drugs. It should be remembered that the main effect of treatment with isoniazid is obtained during the first three months, and, if it has not materialized then, it can hardly be expected later on.

Epidemic (?) Vegetative Neurosis.—Fog reports 10 cases of a disorder characterized by sudden onset, headache, and often malaise and vomiting. In seven cases moderate fever was noted. There were painful paresthesia in the extremities with visible and often pronounced hyperhidrosis, together with symptoms of vascular spasm in the extremities, psycholability, and fatigue. Although precordial pain was frequent, repeated electrocardiograms revealed no changes. The general condition was good. The cerebrospinal fluid, examined in five cases, was normal. The cases occurred during a poliomyelitis epidemic, but paralysis appeared only in one instance, in which the reflexes were lively. The course was marked by fluctuations that gradually decreased and disappeared. In six cases there were marked recurrences at five or six week intervals. The only designation that seems to the author to cover the condition is vegetative neurosis, probably epidemic.

Alloplastic Operation on Hip According to Judet and Pertrochanteric Osteosynthesis in Same Session. R. Movin.—p. 1277.

Chemotherapy in Tuberculosis.—The introduction of isoniazid marks an important advance in the treatment of tuberculosis, but tubercle bacilli rapidly become resistant to the agent when it is applied alone, and, further, there is danger of home treatment because treatment with isoniazid alone is so easily carried out. In order to prevent this valuable agent from becoming ineffective through misuse, Jensen and his associates emphasize that treatment of pulmonary tuberculosis with isoniazid alone is contraindicated except in the case of the few patients in whom the tubercle bacilli are in advance resistant to both streptomycin and *p*-aminosalicylic acid (PAS) and where treatment is required. A long-continued effect of streptomycin or isoniazid can be attained by the combination of each of the substances with *p*-aminosalicylic acid. Combined treatment with all three substances is considered the most effective chemotherapy in tuberculosis. In treatment of patients with tubercle bacilli resistant to streptomycin the combination of isoniazid and *p*-aminosalicylic acid may be recommended, but it must be borne in mind that in about one-fourth of the patients with cavernous pulmonary tuberculosis, tubercle bacilli resistant to isoniazid appear after three months' treatment.

•Treatment of Bechterew's Disease with Thorium X. P. Erlacher.—p. 825.
Formal and Causal Genesis of So-Called "Idiopathic" Aneurysm of Aortic Sinus (Sinus of Valsalva). L. Kucsko.—p. 826.
Problem of Surgical Treatment of Angina Pectoris. W. Weissel, M. Wenzl and G. Wense.—p. 831.

Treatment of Bechterew's Disease with Thorium X.—Thorium X, a radioactive isotope obtained from radiothorium, which gives off only alpha rays and has a half value period of 3.64 days, was used for the treatment of 10 men and 4 women with ankylopoietic spondylarthritis. Men predominated in a ratio of 3 to 1 in contrast to other reports with a ratio of 5 to 1. A buffered solution of 200 electrostatic units of thorium X was injected intravenously once a week for 10 to 12 weeks. Of the 14 patients, 4 became free of complaints, 5 were considerably improved, 1 was a therapeutic failure, and 4 have not been followed up long enough for evaluation of results. The increased erythrocyte sedimentation rate showed a definite tendency to approach normal and the thoracic expansion was increased by 2, 3, and 4 cm. A pain reaction was noted that first occurred in the area most recently involved by the disease and only later in the areas with foci of longer duration. These pains gradually subsided and finally disappeared completely. The patients were able to move more freely; one patient was able to put on his shoes by himself. These satisfactory results corresponded with those reported from the orthopedic clinic of the university in Münster, Germany, by Pitzen whose therapeutic prescriptions were closely followed by the author. Of 120 patients treated by Pitzen between 1948 and 1950, 80 were reexamined after one year; 60 were free of complaints, 18 were considerably improved and only 2 were therapeutic failures. The thoracic expansion was increased on the average from 2.37 cm. before the treatment to 4.35 after the treatment, with an occasional increase up to 8 cm. The treatment should be applied only to inpatients and blood cell counts should be taken regularly. A drop in leukocytes below 4,000 should be considered as a warning sign to reduce the dose of the thorium X.

Epinephrine Ketosis in Diabetes Mellitus.—Müller shows that, whereas epinephrine tolerance tests have been used widely in the study of the carbohydrate metabolism, epinephrine so far has not been employed in testing fat and ketone metabolism. It has long been known that epinephrine reduces the fat content and increases the ketone bodies in the blood, however, with the customary dosage of 1 mg. of epinephrine, injected subcutaneously, ketosis generally does not become evident in the healthy nonfasting person, but it does become manifest whenever the person shows a tendency toward ketosis. It intensifies or makes evident fasting or exertion ketosis, exogenic ketosis resulting after the intake of large amounts of fat, and, of course, the metabolic ketosis of the diabetic patient. Fifty-seven epinephrine tests were made in 33 patients with diabetes mellitus. It was found that after the subcutaneous injection of 1 mg. of epinephrine the fat metabolism of the diabetic patient, even if his sugar metabolism is well adjusted, reacts generally with an increase in blood ketone bodies, but the ketone content generally does not exceed 5 mg. per 100 cc. of blood. Diabetic patients with a decided tendency toward the formation of acetone can be readily detected with the aid of this epinephrine test. Their ketone curves rise much higher, even when their "morning ketone" was normal and their metabolism well adjusted, and the prompt reduction to normal values in four or five hours is lacking. Epinephrine-induced ketosis may prove valuable also in adjusting diabetic patients to a suitable management. However, the epinephrine test cannot be used for the detection of endocrine variants and for differentiating mild and severe forms of diabetes mellitus. It could be demonstrated that glycogenolysis in the liver and ketogenesis are not necessarily interconnected metabolic processes and that the earlier concepts of a retarded fat metabolism, which does not participate in acute combustion processes, can no longer be accepted. It seemed probable that epinephrine first inhibits the combustion of glucose and of ketone bodies in the periphery, and only after the epinephrine effect has been equalized by counter regulation, does intensified combustion begin on an elevated metabolic level.

BOOK REVIEWS

Synopsis of Medical Parasitology. By V. E. Brown, Ph.D., Assistant Professor of Biology, Marquette University, Milwaukee. Paper. $3.50. Pp. 109, with 103 illustrations. V. E. Brown, 512 N. 13th Street, Milwaukee, 1953.

This book is perhaps the first of its kind to be published. It can best be described as a reference manual for the laboratory identification of parasites found in human beings. The subject matter is divided into 31 chapters according to the particular genus, species, or form of each parasite. Each chapter includes a brief discussion of the specified phase of the subject, a list of pertinent references, and a series of drawings to illustrate the morphology of the parasite and its life cycle. The illustrations constitute the most important feature of the book and consist of uncolored reproductions from structurally precise scale drawings showing the microscopic anatomy of the various cyclic forms as they are known to occur in man, vector, and intermediate or definitive host. The external appearance of certain insects or animals involved as vectors, intermediates, or hosts is also illustrated. The illustrations of parasites are carefully labeled and accompanied by a key to the identity of all important anatomic features. The author intends the publication for students who cannot afford and find it inconvenient to use the large number of texts on the subject that should be consulted in the laboratory. From that standpoint, the book will be useful as a teaching supplement to lectures and textbooks on the subject. A general index included at the end increases the usefulness of the manual as a reference. Some of the entries refer to names that are not listed in the text. This is likely to be confusing to beginners.

This publication will be useful as a supplement to other sources of instruction, chiefly from the point of view of laboratory diagnosis.

Plant Proteins in Child Feeding. By R. F. A. Dean. Medical Research Council special report series no. 279. Paper. $2.25; 10s. Pp. 163, with illustrations. British Information Service, 30 Rockefeller Plaza, New York 20; Her Majesty's Stationery Office, P. O. Box 569, London, S.E.1, 1953.

In many parts of the world it is difficult or impossible to obtain sufficient milk for the feeding of infants and children. Therefore, the development of foods that could be prepared from indigenous raw materials is of great practical value. During the years 1946 to 1949, Prof. R. A. McCance of the University of Cambridge headed a Medical Research Council team studying undernutrition in Germany. Dr. Dean, a member of this group, investigated the value of mixtures of plants as additions to children's diets. His findings are reported in this book, which is divided into two parts. The first reviews the problems in the use of plant proteins for human nutrition, and the second gives the actual data obtained in Dr. Dean's studies and his recommendations for future work.

The children, who were living in orphanages, varied in age from 6 months to 11 years and were fed basic diets containing little animal protein for periods of 8 to 24 weeks. These were supplemented with cow's milk or mixtures of cereal and soya. It was found that a large portion of the children's diets could consist of the cereal and soya mixture with no adverse effect on growth. In the meals of children below the age of one year, about half the total amount of milk could be replaced with the plant proteins. The replacement of almost all of the milk with plant proteins could be accomplished with the older children, although for optimum growth a small amount of milk seemed to be necessary. Dr. Dean concludes that it may ultimately be possible to provide mixtures of foods, derived entirely from plant sources, that would equal milk in nutritive value. Pediatricians and others who are concerned with the feeding of infants and children in areas where milk is not readily available will find this publication valuable. Other physicians and students interested in nutrition in general can glean much from the discussion of the use of proteins of plant origin in the human diet.

Die Nahbestrahlung. Von Henri Chaoul und Felix Wachsmann, Dozent für medizinische Physik an der Universität Erlangen. *Second edition.* Cloth. 39 marks. Pp. 225, with 304 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart-O; American agent, Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This book offers a complete and up-to-date description of the techniques used in applying soft roentgen radiation to superficial or to surgically exposed lesions (plesio-roentgentherapy, contact roentgentherapy, and low-voltage near-distance therapy). Well illustrated with photographs of apparatus and cases, it contains much valuable quantitative information in the form of tables and diagrams. Radium and the radium-substitutes recently provided by the uranium pile are excluded from the discussion except for purposes of comparison. The text is well written, the printing excellent, and the extensive bibliography includes Italian, French, English, German, and American work. The use of such abbreviations as FHA and GHWT is annoying. In some places their meaning is evident from the context, but in others it is not; often the reader could be saved time and effort by a single entry in the index leading to the passage where the abbreviation is explained or first used. Aside from this and a few small errors in the bibliography, the book deserves high praise. It will probably prove to be a classic in its field.

Vegetative Konstitutionstherapie. Von Otto Hauswirth, Facharzt für physikalische Medizin in Wien. Cloth. $5.45. Pp. 298, with 23 illustrations. Springer-Verlag, Mölkerbastei 5, Wien 1, 1953.

Conceived as a pioneer work to explore the relation of constitution to therapy, this book begins with some undeniable anatomic facts about the autonomic nervous system, moves on to the shaky ground of human typology, and then attempts to explain practically everything in pathology, pharmacodynamics, and physical therapy in terms of vagotonia and sympathicotonia. The effects of various antibiotics are explained by their assumed effects on the nerves (pages 146 to 150). Sunlight (page 256) is stated to cause a discharge of electrons from the skin by the familiar process of photoelectric emission, so that the vagus loses its charge and lets the sympathetic nerves get the upper hand; hence one need only ask a patient whether he tolerates sunlight, for if he does he is a vagotonic. There are no indications that the author appreciates the importance of contratests or understands statistical methods; his ideas are based on a diligent but uncritical exegesis of about 700 items of medical literature listed in his bibliography. This book, which is not recommended, makes one wish for a "new deal" in medical literature.

The Conquest of Plague: A Study of the Evolution of Epidemiology. By L. Fabian Hirst, M.D. With foreword by Lieut.-General Sir William Macarthur, K.C.B., M.D., F.R.C.P. Cloth. $11. Pp. 478, with 26 illustrations. Oxford University Press, 114 Fifth Avenue, New York 11; Amen House, Warwick Sq., London, E.C.4, 1953.

This book is not a history of plague epidemics or a systematic textbook. It begins with a brief account of traditional beliefs about the cause of plague, then traces the main source of human infection to the ubiquity of rats and fleas. It ends by showing how recent advances in our knowledge of rats and their parasites has led to the conquest of this deadly disease. The author, who has had long experience with this disease in the Middle and Far East, has written in a lucid style that should attract lay persons as well as physicians. The book is comprehensive and contains an adequate bibliography at the end of each of its four parts. Four appendixes give technical information considered too detailed for the main text. There is an author index and a subject index.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

Hunted Heretic: The Life and Death of Michael Servetus, 1511-1553. By Roland H. Bainton. Cloth. $3.75. Pp. 270, with illustrations. Beacon Press, 25 Beacon St., Boston 8, 1953.

This is a biography of the 16th century scholar, Servetus, who, like his contemporaries of the Renaissance, was thirsty to conquer all fields of knowledge. He was a distinguished student of the Bible, a theologian, geographer, physician, physiologist, and a master of ancient languages. Although such a combination is very rare today, it must be remembered that in those days theology, philosophy, physiology, and psychology were not compartmentalized but were all a part of advanced learning. As a result, the practice of medicine appears to have been but one of several sidelines for Servetus. The author points out that Servetus discovered that the blood circulates through the lungs, a fact that Galen had not understood, but most of the book is devoted to a discussion of the religious controversies that finally led to Servetus' being burned as a heretic. The author states that Servetus "was never quite sure whether he was talking the language of physiology or religion and, for that reason, he has become difficult to comprehend in an age of secularization of science. For [him] there was only an enhancement of natural processes in ascending from respiration to inspiration, generation to regeneration, from sight to insight, from birth to new birth of the spirit." In another passage the author makes the profound observation that "two religions can exist side by side amicably only if they think they can." This book will appeal to those who like to browse in history. At the end there is a chronology, a bibliography, annotations, and an index.

The Physics of Radiation Therapy. By Harold Elford Johns, M.A., Ph.D., F.R.S.C., Professor of Physics, University of Saskatchewan, Saskatoon, Canada. Publication number 116, American Lecture Series, monograph in Bannerstone Division of American Lectures in Radiation Therapy, edited by Milton Friedman, M.D., Associate Professor of Radiology, New York University Post-Graduate Medical School, New York. Cloth. $8.50. Pp. 286, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad Street, Oxford, England; Ryerson Press, 299 Queen Street, W., Toronto 2B, 1953.

The author's purpose is to explain, for students and physicians, the physical principles basic to an understanding of radiotherapy. The first chapter on the nature of matter and of radiation is followed by six chapters on roentgen rays, one on energy absorption, two on radium, one on high energy devices such as the betatron, and one on artificial radioactivity with emphasis on the therapeutic use of materials like cobalt 60 that emit gamma rays. Two appendixes supply a wealth of precise technical information in the form of tables and diagrams. There are many good illustrations, a subject index, and an author index, and the book as a whole is legible and attractive. It can be recommended both as an introduction for students and as a reference work for specialists using ionizing radiations therapeutically.

History of the Second World War: United Kingdom Medical Series. Editor-in-Chief: Sir Arthur S. MacNalty, K.C.B., M.D., F.R.C.P. The Emergency Medical Services. Volume II: Scotland, Northern Ireland and the Principal Air Raids on Industrial Centres in Great Britain. Edited by Lieut. Colonel C. L. Dunn, C.I.E., I.M.S. Cloth. 50s. Pp. 492, with 40 plates. Her Majesty's Stationery Office, P. O. Box 569, London, S.E.1, 1953.

Volume 2 of this historical series is in three parts. Parts 1 and 2 show that the emergency medical services adopted in Scotland and Northern Ireland followed a pattern similar to those that proved their worth in England and Wales. The latter were briefly mentioned in a review of volume 1 published previously in The Journal (Aug. 15, 1953). Great encouragement is to be derived from reading these two volumes, as they show the remarkable adaptability possible during wartime in a highly complex society crowded together in large cities. Scotland was subjected to a greater number of air attacks than is generally known, and some of them were severe. There were very few enemy air attacks in Northern Ireland except for Belfast, but, during one of the four raids on that city, more persons were killed in about six hours than in any day raid in England made outside of the London area. Part 3 of this volume gives a representative picture of the various emergency medical services in action under the strain of heavy air attacks by the enemy; it also includes accounts of some of the "Baedeker" raids in 1942, when the enemy began heavy attacks on the cathedral cities of Exeter, Bath, Norwich, York, and Canterbury. Hitler threatened to ruin every cathedral city mentioned in "Baedeker." In this section of the volume it is said that the emergency medical services functioned most efficiently. Civil defense workers will be interested not only in the effectiveness of the Emergency Medical Services but also in some of the mistakes made. For example, on page 459 in the account of the raids on Belfast, it is said that in the larger raids, the mistake made by the control center was the calling of excessive resources from outside areas. At one time more than 120 first aid parties and ambulances were in a most vulnerable area in the center of the city. Most of the country parties called into the city had nothing to do. It was a mistake to put first aid posts in the "externs of hospitals." The result was that, during the raids, the externs became filled with the wounded, the dying, and the dead, and the actual work for which the first aid post was intended could not be carried out efficiently. The number of casualties from air raids in the London area from September, 1939, to June, 1942, is tabulated on page 210. The total number killed is given as 20,102, the injured (detained in hospitals) as 26,054, and the slightly injured as 47,046. These figures are only approximate because after heavy raids many fatalities were not discovered for days and others had to be eventually recorded as missing, presumed dead. There were also hundreds of fragments of human remains from which it was not possible to make any identification.

While this volume was prepared under the direction of an editorial board appointed by his Majesty's Government, the authors and the editors alone are responsible, it is said, for the opinions expressed. Just where this responsibility lies is a little difficult to determine because of the numbers who took part in preparing this volume. On the jacket and the flyleaf it is said to have been edited by C. L. Dunn. On a following page are the names of many who served on the editorial board, the chairman of which was Sir Cyril Flower. On another page are the names of those who served on the editorial committee, of which Sir Arthur S. MacNalty was chairman.

May's Manual of the Diseases of the Eye for Students and General Practitioners. Edited by Charles A. Perera, M.D., Associate Clinical Professor, College of Physicians and Surgeons, Columbia University, New York. Twenty-first edition. Cloth. $6. Pp. 512, with 378 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

Adhering to the original purpose, the author has given us a simple, lucid, and concise text for medical students and general practitioners. He has revised each chapter and has added some new color plates. Future editions should omit some of the more obsolete forms of treatment such as the use of the copper sulfate stick in the treatment of trachoma. Each chapter has a short description of the normal anatomy and physiology of the conditions described. Nothing that is still of a controversial nature or in a semi-experimental stage has been included. The book should continue to be very popular, especially with medical students.

Elementary Pathological Histology. By W. G. Barnard, F.R.C.P., Professor of Pathology, University of London, St. Thomas's Hospital Medical School, London. Third edition. Cloth. 17s.6d. Pp. 77, with 185 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1, 1953.

No major changes are made in the revision of this guide for students beginning elementary general pathology. Accordingly, concepts expressed in previous editions are continued despite recent changes in generally accepted viewpoints. The material illustrates the histology of the three principal pathological processes: inflammation, degeneration (retrogressive changes), and tumors. The treatment is general, in the belief that, from this understanding, the histology of special pathological lesions can be understood. The photomicrographs are average in quality, and the drawings are good. It is doubtful that the book will be used to any extent by beginning students of pathology in this country.

QUERIES AND MINOR NOTES

TRANSFUSION REACTIONS

To the Editor:—*Regarding the use of isotonic and dilute sodium chloride solutions in starting blood transfusions, is it hazardous to use 5% dextrose in distilled water for this purpose? Is it safer to use saline solution with or without 5% dextrose for this purpose?*

T. F. Brinton, M.D., Eugene, Ore.

Answer.—It is inadvisable to administer dextrose solutions with citrated whole blood. De Gowin, Hardin, and Alsever (Blood Transfusion, Philadelphia, W. B. Saunders Company, 1949, p. 278) have called attention to the danger of extravascular hemolysis resulting from the mixture of stored blood and dextrose solutions. Although the clumping that occurs in a mixture of dextrose solution and citrated whole blood is reversible, Wilson (*Am. J. Clin. Path.* 20:667, 1950) has reported a transfusion reaction traceable to this phenomenon. Dreyfus and Salmon (*Presse méd.* 60:845, 1952) have also pointed out the danger of clumping and of increased fragility of red blood cells exposed to dextrose solutions. They have presented results of in vitro and in vivo studies to support their conclusion that the practice of giving simultaneous infusions of dextrose solutions and whole blood should be abandoned.

SENSATION OF BURNING IN ESOPHAGUS AFTER GASTRECTOMY

To the Editor:—*A patient who had a total gastrectomy for carcinoma a year ago with excellent results has suffered ever since with a constant burning throughout the esophagus. He is at work, feels well, and does not gain weight. Can you suggest an explanation for this symptom?*

M.D., California.

Answer.—Sensations of burning in the esophagus following total gastrectomy are often due to the regurgitation of bile and duodenal secretions into the lower esophagus and even occasionally into the pharynx. This regurgitation is most likely to occur when the lower end of the esophagus has been anastomosed to the side of the first part of the jejunum without an accompanying enteroenteric anastomosis lower down. The disagreeable symptoms usually disappear in time and are relieved somewhat if the patient sleeps with the head and shoulders somewhat elevated. The oral administration of bismuth preparations or of aluminum hydroxide gel (Amphojel) sometimes gives marked relief.

DUPUYTREN'S CONTRACTURE

To the Editor:—*I should like to know the present concepts regarding the causes of Dupuytren's contracture and regarding the role of working conditions as an aggravating factor. What supportive therapy is of value? Is corrective surgery advisable and at what stage? Is it advisable for such men to continue to work, considering work as a natural physiotherapeutic exercise?*

P. Guiraud, M.D., New York.

Answer.—The cause of Dupuytren's contraction is still a matter of uncertainty. There is no evidence that hard and vigorous use of the hand either causes or aggravates the condition. More than half the patients in carefully recorded series were men who did little work that involved active use of the hands. There is no medical treatment of value. The one certain method of correcting the condition is carefully performed, wide excision of the contracted fascia. The operation should be done if the overlying skin is becoming involved to such an extent that removal of the skin and subsequent skin grafting would be necessary to secure a good result or if a finger is being drawn down into the palm and the thickening and contraction of the fascia is producing a flexion contracture. Early operation in the absence of skin involvement and beginning contracture does not seem advisable, because similar development may occur in some other part of the hand, and a second operation may be required at a later date.

WILMS' TUMOR IN INFANT

To the Editor:—*An 8½-month-old white girl has undergone surgery for the removal of a Wilms' tumor (nephroblastoma) on the left side. Despite its removal, hypertension ranging from 200 to 250 mm. Hg systolic and 100 to 140 mm. Hg diastolic persists one week after surgery. The child has received sedation, has been given abdominal radiation on two occasions, and is on a low salt diet. She does not appear to be in acute distress. Her respirations and pulse rate are only slightly elevated. There is no mechanical error in recording the pressures, and other causes of hypertension have been "ruled out." In view of the relative asymptomatology, should attempts be made to bring the infant's tension down by the use of hydralazine (Apresoline) hydrochloride and related drugs? Should prophylactic digitalization be instituted in view of possible myocardial failure? What would be the approximate maintenance schedule if adrenolytic drugs were tried?*

Louis E. Imperiale, M.D., Brooklyn, N. Y.

Answer.—Wilms' tumor and hypertension have been associated in occasional patients. Pressure produced by involved lymph nodes about the renal pedicle may interfere with arterial blood supply and cause nephrogenic hypertension. The elevation of blood pressure associated with Wilms' tumor has not, however, been so great as that described in the query. Cerebral metastasis may cause great elevation of blood pressure associated with increase of intracranial pressure. Hypotensive drugs should be used cautiously. It is not likely that digitalization would help. Ganglionic blocking or adrenolytic drugs, if used, should be administered parenterally in minute doses at first and then in larger increments until an effect is evident. This would determine the initial maintenance requirement. Subsequent rise of blood pressure might necessitate larger doses after days or weeks of treatment.

RETINITIS PROLIFERANS

To the Editor:—*A man, aged 20, has had diabetes mellitus since the age of 3½. He has been growing progressively "blind" since October, 1952. He was seen by a prominent ophthalmologist, who told him that nothing could be done for him. His diabetes is controlled by 20 units of regular insulin three times daily. He is well developed and is 6 ft. (182.88 cm.) tall. Can you advise anything that may arrest the condition?*

Max D. Goldman, M.D., Brooklyn.

Answer.—The history of this patient suggests that retinitis proliferans has developed, which is the main ocular complication of diabetes in the young. In all patients with retinopathy, lack of control of the diabetes precedes the development of the ocular signs. Prophylaxis by adequate control of the diabetes with prevention of this complication is the only effective method of treatment. Unfortunately once the retinopathy has developed, there is no proved therapy of value. Through the years many remedies have been proposed and then discarded. Recently it has been suggested that vitamin B_{12} might be of value, together with x-ray therapy to combat the neovascularization of the retinitis proliferans. Testosterone propionate has been suggested, as have rutin and vitamin C, but their use is falling into discard.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

THYROIDECTOMY

To the Editor:—*Is thyroidectomy indicated in the following case? A 30-year-old white woman is married and has three children. Her father and a niece have tuberculosis. On Jan. 9, 1953, while receiving an injection for varicose veins, she complained of nervousness and palpitation. Her basal metabolic rate was +26%. She was given strong iodine (Lugol's) solution for two weeks. Thyroidectomy was considered. The thyroid gland was barely palpable, and the rest of the physical examination revealed no pertinent abnormalities. X-ray examination, blood count, and urinalysis also revealed no abnormalities. On Jan. 30, 1953, her basal metabolic rate was +40. Her blood pressure was 125/80 mm. Hg, the pulse rate 132, and weight 112 lb. The patient is sensitive to smoking cigarettes; her pulse before smoking is 82 and after smoking 144, with little change in blood pressure. When she stopped smoking the nervousness and palpitation ceased and she felt fine. On March 18 the metabolic rate while she was under sedation with thiopental (Pentothal) was +4. On May 5 diagnostic currettage was done for profuse menstrual bleeding. On May 8 the metabolic rate was +38 and she was placed on propylthiouracil therapy, 300 mg. daily. On July 8 the metabolic rate was +24 and she weighed 114 lb. She felt well and had no symptoms. The blood pressure was 120/75 mm. Hg and the pulse 84. The patient has a definite dread of the procedure for determining the basal metabolic rate.*

Carl B. Adams, M.D., Adams, N. Y.

Answer.—The clinical history and the objective findings in this patient do not reveal much conclusive evidence for hyperthyroidism. Little importance can be attached to the basal metabolic rate determination in a patient who is as excitable and resistant to the basal metabolism procedure as this one appears to be. Furthermore, it is clear that at times she feels well even when her basal metabolism is reported high. In many patients mild hyperthyroidism like this is well controlled by propylthiouracil and after a year of treatment will remain in remission indefinitely. Certainly unless a more definite diagnosis can be made, utilizing additional laboratory procedures such as determination of the cholesterol and protein-bound iodine levels and tracer determinations with radioactive iodine, there is no indication at this time for operation. Since many thyroids are removed unnecessarily in the treatment of symptoms suggesting, but not arising from, hyperthyroidism, it is important that there be strong objective evidence of hyperthyroidism before definitive treatment is given.

MULTIPLE MYELOMA

To the Editor:—*Is a total protein value in excess of 9 gm. per 100 cc. with more than 3 gm. of globulin indicative of multiple myeloma? Would a total protein level of 4.5 gm. per 100 cc., with 4.1 gm. of albumin and 0.4 gm. of globulin, necessitate cancellation of surgery (gallbladder)? Is determination of total protein a routine preoperative procedure? What are the chief laboratory diagnostic criteria in multiple myeloma?*

M.D., New York.

Answer.—It would be difficult to answer the first part of this question without knowing the exact value of the globulin. In multiple myeloma there is commonly a reversal of the albumin-globulin ratio, with a high globulin value while the albumin value remains within the limits of normal. Reversal of the albumin-globulin ratio with a high globulin level occurs in a number of other conditions and cannot be considered specific for myeloma. It is commonly seen in sarcoidosis, disseminated lupus erythematosus, and lymphogranuloma venereum, and it may occur in acute infections, blood dyscrasias such as leukemia, and kala-azar.

A total protein value of 4.5 gm. per 100 cc. with a globulin value of 0.4 gm. and an albumin value of 4.1 gm. is most unusual. It would be proper to question whether or not the method for protein determination was being properly carried out. While a globulin value of 0.4 gm. may be seen, one would expect to see with it a marked reduction in the albumin such as may occur in nephrosis. Determination of the total protein level is certainly not a preoperative procedure routinely. The chief laboratory diagnostic criterion in multiple myeloma is the examination of either sternal bone marrow or direct biopsy of the lesion with demonstration of myeloma cells.

TESTOSTERONE FOR OLDER MEN

To the Editor:—*What are the contraindications to the use of testosterone in small (10 mg.) daily doses? Are there any harmful results in the prolonged use in men when it seems to produce a sense of well-being and greater activity? Is this imaginary or real improvement? What daily dose is recommended?*

M.D., Arkansas.

Answer.—It is assumed that the question refers to the use of testosterone in daily doses of 10 mg. by mouth in older men. The only harmful effect definitely established is the production of breast enlargement in a small percentage of men who receive it. It should not be used if there are any findings to suggest the presence of carcinoma of the prostate; however, carcinoma of the prostate cannot be induced by the use of testosterone. If carcinoma is present, its growth may be accelerated by the use of testosterone. A sense of well-being and greater activity are commonly observed in older men who take it and are probably not imaginary. The presence of actual improvement can be determined in many individual cases only by careful study.

CHLOROPHENOTHANE (DDT) IN WATER SUPPLY

To the Editor:—*Is it an accepted procedure to add chlorophenothane (DDT) to the water supply of a city? The water comes from springs in mountainous country and is collected in reservoirs. The proposed dosage of chlorophenothane is 10 gm. per cubic meter in biweekly intervals. What kind of parasites or pathogenic organisms would be eliminated? Would the domestic use of this water give rise to untoward reactions. Would the chlorophenothane content of used, stagnating water be sufficiently high to prevent development of Anopheles or Aedes aegypti mosquitoes? Is there any simple method of eliminating the chlorophenothane from the drinking water in private households?* *M.D., Haiti.*

Answer.—Treatment of an entire water supply of a community with chlorophenothane is not a recognized public health procedure. When mosquito control operations are in effect and it is necessary to kill mosquito larvae, it may be necessary to treat the surrounding edges of a water reservoir, particularly when vegetation or aquatic growth is present. This type of limited treatment has been effectively carried out using 0.05 to 0.1 lb. (24 to 48 gm.) of chlorophenothane per acre or by using about 6 gal. (24 liters) of no. 2 diesel oil per acre with a spreading agent.

Anopheline larvae will be found breeding in open type reservoirs and impounded water areas, but Aedes aegpti breed in artificial containers such as bottles, tin cans, flower vases, tanks, and cisterns. If the water supply is in cisterns, control may be obtained by applying a 1% residual chlorophenothane spray on the walls or linings of the cistern or applying a pyrethrum larvicide to the water surface.

The proposed dosage of 10 gm. per cubic meter of chlorophenothane is about 10 ppm. It is generally recommended that a concentration of 1 ppm in a drinking water supply will control Anopheles quadrimaculatus larvae. This concentration is not considered detrimental to the health of man. It is highly improbable that this insecticide will eliminate any parasite or pathogenic organism. It is felt that use of an activated carbon filter would remove much of the taste of fuel oil, chlorophenothane, or other foreign matter from the water supply. Additional technical information and guidance can be secured from the Communicable Disease Center, U. S. Public Health Service, 50 7th St., Atlanta, Ga.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, SEPTEMBER-DECEMBER 1953

Titles have been listed or abstracts made of important articles in the following journals in the Current Medical Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to individual subscribers in Continental United States and Canada and to members of the American Medical Association and its student organization. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical. Three journals may be borrowed at a time for a period not exceeding five days. Requests should be addressed to the Library of the American Medical Association. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 1653.

A

ACTH: See Corticotropin
Ak LEUKEMIC EXTRACTS
  filtrable agent causing mouse salivary gland carcinoma, 150—E
Au^{198}: See Gold, radioactive
ABDOMEN: See also Ascites; Gastrointestinal Tract; Peritoneum
  acute conditions at emergency service, Chilean hospital, 1111
  acute conditions in infantile diarrhea, Mexico, 234
  emergencies in newborn, [Cooper & others] *1079
  retroperitoneal masses, percutaneous femoral artery aortography for, [Peirce] 757—ab
  Retropneumoperitoneum: See Retropneumoperitoneum
  Surgery: See also Cesarean Section
  surgery, liver nodules found at laparotomy, [Mixter] 1049—ab
  tumors (retroperitoneal) cause of low back and leg pain, [Anderson] 1052—ab
  Viscera: See Viscera
ABNORMALITIES: See also Crippled; Monsters; under specific organ and region as Heart; Lungs
  congenital, and excessive vitamin A, 1176—E
  in infant after maternal rubella, [Tedeschi] 1483—ab
  100 Japanese children exposed in utero to detonation of atomic bomb, 218—E
  rubellar embryopathy, [Malbran] 886—ab
  Turner's syndrome, (in female), [Jackson] 1217—ab; (in male) [Sougin Mibrohan] 1217—ab
ABORTION
  criminal, eight years ago: any residual physical signs? 1232
  criminal, potassium permanganate as abortifacient, London, 1301
  habitual, caused by wide uterine isthmus, [Swaab] 767—ab
  legal, statistics, Sweden, 1569
  missed; was patient pregnant? 607
ABSCESS: See also Ulcers; under organs affected
  chronic, streptokinase-streptodornase in enzymatic decortication, [Halse] 687—ab
  sterile, after immunization, 1067
ABSENTEEISM: See Industrial Health, workers absenteeism
ABSORPTION: See Malabsorption Syndrome
ACADEMIC FREEDOM
  in military medical research, [Karsner & Phillips] *1356
ACADEMY: See under name of specific academies as American Academy; list of societies at end of letter S
ACCELERATOR
  Linear: See Linear Accelerator
ACCIDENTS: See also Casualties; Disasters; Trauma
  A.M.A. exhibit on, 434
  among teen-agers, 572
  Automobile: See Automobiles
  farm, 34—E
  fatal; experiences under Ohio coroner's system, [Landé & Boone] *179
  fatal; leading causes of death, 1177—E; (Alaska) 1371
  firearm, prevention of, 1365—E
  home, prevention program by W. K. Kellogg Foundation, Ky., 37
  Industrial: See Industrial Accidents
  Insurance: See Medicolegal Abstracts at end of letter M
  Prevention: See also National Safety Council
  prevention, courses in, N. Y., 1290
ACE Elastic Hose (for Men), 1285
ACETONE
  examination of tissue sections, (replies) [Wright; Pickard] 1328
ACETYLCHOLINE
  treatment, injection, combined with epinephrine in atopic dermatitis, [Lobitz] 512—ab
ACHALASIA: See Stomach cardiospasm
ACHYLIA gastrica: See Stomach
ACID
  acetylsalicylic, plus *p*-aminobenzoate in rheumatoid arthritis, [Zarafonetis] 1120—ab
  acetylsalicylic, treatment of nonbacterial respiratory infections, [Jones & others] *262
  Amino Acids: See Amino Acids
  p-aminobenzoic plus acetylsalicylic acid in rheumatoid arthritis, [Zarafonetis] 1120—ab
  p-aminosalicylic, and dihydrostreptomycin, effect in artificial pneumothorax [Birath] 1210—ab
  p-aminosalicylic, N.N.R., (Sharp & Dohme), 727
  p-aminosalicylic, plus streptomycin and thiosemicarbazone in tuberculosis, Turkey, 1471
  p-aminosalicylic plus streptomycin in pulmonary tuberculosis, [Medical Research Council] 1059—ab
  p-aminosalicylic, plus streptomycin in renal tuberculosis, [Lattimer] 172—ab
  p-aminosalicylic, sodium salt, N.N.R., (Chemo Puro; Merck) 727, (Pasmed of Intermedico) 1447
  p-aminosalicylic (sodium), thrombocytopenia induced by, [Wurzel & Maycock] *1094
  p-aminosalicylic, streptomycin, and isoniazid combined for tuberculosis, Denmark, 1300; [Jensen] 1594—ab
  p-aminosalicylic, "swing therapy" in pulmonary tuberculosis, [Tanner] 1407—ab
  p-aminosalicylic, used in tuberculosis, streptomycin resistance after, [Turnbull] 251—ab
  p-aminosalicylic, vs. 5 other agents used in pulmonary tuberculosis, [Tempel] 589—ab
  ascorbic, and adrenal cortex, Italy, 1467
  ascorbic, intimal ground substance in atherosclerosis, [Willis] 685—ab
  ascorbic, sodium salt, N.N.R., (Vitarine) 925
  ascorbic, treatment of anemia, [Spies] *188
  ascorbic, 25 mg. neutralized in body by smoking 1 cigarette, 527
  ascorbic—U.S.P., N.N.R., (Rexall) 727
  ascorbic, vitamin C deficiency, 527
  Barbituric; See Barbiturates
  Carbolic: See Phenol
  Cevitamic: See Acid, ascorbic
  folic, and vitamin B_{12} treatment of pernicious anemia, [Spies] *190
  folic, excretion test in intestinal malabsorption [Girdwood] 765—ab
  folic, liver extract, and vitamin B_{12} in pernicious anemia, [Canelas] 1215—ab
  folic, treatment of anemia, [Spies] *188
  Folic, Antagonists: See Aminopterin
  [illegible] acidity
  [illegible] ly for cholecysto- [illegible] & Caffey] *1333
  iodoalphionic (Priodax), pseudoalbuminuria after [Holoubek & others] *1018
  iodopanoic (Telepaque), orally for cholecystography in infants, [Harris & Caffey] *1333
  iodopanoic (Telepaque), pseudoalbuminuria after [Holoubek & others] *1018
  Isonicotinic Hydrazide: See Iproniazid; Isoniazid
  nicotinic, treatment of psychiatric syndromes, [Levy] *1260
  oxalic, to remove permanganate stains, (replies) [Palmer; Evans] 894
  sulfuric, esophagus injury from swallowing, [Dogliotti] 1488—ab
  sulfuric, tubercle bacilli isolated after pretreatment with, [Weigand] 71—ab
  Uric: See Uric Acid
ACIDITY
  Gastric: See Stomach acidity
ACIDOSIS
  Diabetic: See Diabetes Mellitus
ACNE: See also Furunculosis
  treatment, ultraviolet rays, prolonged use on face harmful? 776
ACROMELALGIA: See Erythromelalgia
ACTH: See Corticotropin
ACTINOMYCES, Antibiotic Prepared from: See Streptomycin
ACTINOMYCOSIS
  effect of DDS on Nocardia brasiliensis, Mexico, 446
ACTINOMYCOSIS—Continued
  in Scotland, 1568
  treatment, aureomycin, [McVay] 59—ab
  treatment, isoniazid, [McVay & Sprunt] *95
ACTIVITY: See Exercise
ADAEQUAN: See Blood proteins
ADAMS-Stokes Syndrome: See Heart, block
ADDICTION: See Alcoholism; Barbiturates; Narcotics
ADDISON'S ANEMIA: See Anemia, Pernicious
ADDISON'S DISEASE
  kinetic conception [Bastenie] 1226—ab
  treatment, long-acting desoxycorticosterone, [Sorkin] 1317—ab
ADDRESSES: See Lectures
ADENITIS: See Lymphatic System
ADENOIDECTOMY
  in children, endotracheal anesthesia for, [Pender & Hallberg] *1073
  poliomyelitis relation to, [Hayes] 1481—ab
ADENOLIPOMA
  of thyroid: new type of goiter, [Chesky] 521—ab
ADENOMA
  of lung, [Hutchison] 1583—ab
  peripheral and multiple bronchial, [Felton] 60—ab
  Nontoxic, of Thyroid: See Goiter
  renal, [Childs] 1405—ab
  Toxic, of Thyroid: See Goiter, Toxic
ADIPOSITY: See Obesity
ADOLESCENCE
  accidents among teen-agers, 572
  kyphosis, [Dameron] 250—ab
ADRENALECTOMY: See Adrenals, surgery
ADRENALIN: See Epinephrine
ADRENALS: See also Addison's Disease
  Adrenocorticotropic Hormone: See Corticotropin
  cortex and ascorbic acid, Italy, 1467
  cortex and biology of cortisone, Italy, 1467
  Cortex Compound E: See Cortisone
  Cortex Hormone (Crystalline): See Desoxycorticosterone
  cortex, insufficiency, kinetic conception, [Bastenie] 1226—ab
  cortex, interdependence of stress and, in carbohydrate metabolism, [Burns] 979—ab
  cortex, pneumographic diagnosis of hyperadrenocorticalism, Italy, 1468
  etiologic role in hypertension, [Wilson] 1587—ab
  hormone metabolism in paraplegia, [O'Connell & Gardner] *709
  Hormone (Sympathetic): See Epinephrine
  roentgen study after retropneumoperitoneum, Italy, 1468
  surgery, adrenalectomy-sympathectomy combined in essential hypertension, [Zintel] 1403—ab
  surgery and sympathectomy in severe hypertension, [Jeffers] 880—ab; [Jeffers & others] *1502
  surgery, bilateral adrenalectomy in advanced neoplasms, [Barker] 1319—ab
  surgery, bilateral adrenalectomy in Cushing's syndrome, 567—E
  surgery, bilateral total adrenalectomy in prostate cancer, [Blunden] 1319—ab
  surgery, changes in prostatic cancer after adrenalectomy, [Franks] 1216—ab
  surgery, estrogen excretion in breast cancer before and after adrenalectomy, [Dao] 761—ab
  surgery for Cushing's syndrome, [Poutasse] 1051—ab
  tumors, familial bilateral pheocromocytoma: successful removal in siblings, [Roth] 676—ab
  tumors, neuroblastoma of medulla, Turkey, 1471
ADRENOCORTICOTROPIC HORMONE: See Corticotropin
ADVERTISING
  food acceptance and, (report) 938
  State Journal Advertising Bureau: See American Medical Association

ADVISORY
  Board for Medical Specialties, [Kirklin] *339
  Commission: See Citizens Advisory Commission
  Committee, joint meeting on rural health, 733
  Committee on Internships, (Council report) *278; (report) 943
AEROMEDICINE: See Aviation medicine
AERONAUTICS: See Aviation
AEROSOLS
  Administration by: See Trypsin
AEROSPORIN: See Polymyxin B Sulfate
AFIBRINOGENEMIA: See Blood
AFRICA
  kwashiorkor, (Council article) [Williams] *1280
  sanitation programs in, and human factors, 705—ab
AFRICAN VIOLETS
  flowering hobby, [Leisure Corner] *55
AFTERBIRTH: See Placenta
AGE
  Adolescent: See Adolescence
  at time of death in distinguished and undistinguished physicians, [Poynton] 1379—C
  breast cancer and, Norway, 663
  essential hypertension; prognosis and course, [Palmer & Muench] *1
  middle, inguinal hernia in men over 55, [Debenham] 882—ab
  myasthenia gravis and, [Schwab & Leland] *1270
  Old Age: See Old Age
  thyroid cancer prognosis and, [Crile] 679—ab
AGGLUTINATION
  of "free-living" endamoeba trophozoites by human serum, Brazil, 47
  of Treponema pallidum in syphilitic serums, [McLeod] 761—ab
AGGLUTININS
  Rh: See Rh Factor
AGGLUTINOGEN
  Rh: See Rh Factor
AGRANULOCYTOSIS
  cyclic neutropenia (at 21-day intervals); splenectomy for, [Coventry] *28
  etiology: phenylbutazone and 4-amino-antipyrine, [Kiely] 594—ab
  immunologic, [Hansen] 67—ab
AGRICULTURE: See Farm
AIR: See also Oxygen
  Ambulance: See Ambulances
  Compressed: See Caisson Disease
  conditioning, relief for hay fever patients, 1066
  cysts (pulmonary), [Harden] 62—ab
  Dust in, as Industrial Hazard: See Pneumonoconiosis
  fresh air therapy in tuberculosis, [Placak] *796
  Injection: See Pneumoperitoneum; Pneumothorax, Artificial
  pollution, meeting on, Indiana, 569
  pollution, research on, Calif., 1556
  Presence of Air in Cavity: See Pneumoperitoneum; Pneumothorax
  smog, London, 1566
  smoke and cancer, London, 1039
  spaces (abnormal) in lungs, [Mayer & Rappaport] *700
AIR FORCE: See Aviation, U. S. Air Force
AIR PASSAGES: See Respiratory System
AIRPLANES: See Aviation
β-ALANINE
  treatment of malaria, Brazil, 1195
ALBEE Lecture: See Lectures
ALBERT Fellowship: See Fellowships
ALBUMIN
  in Blood: See Blood proteins
  in Urine: See Albuminuria
ALBUMINURIA
  Pseudoalbuminuria: See Pseudoalbuminuria
  routine tests for: heating method and nonheating chemical methods compared, 692
ALCOHOL
  Addicts: See Alcoholism
  amount that can be tolerated, 1414
  blood alcohol concentration, (correction) 439
  blood alcohol concentrations in relation to drinking wine, [Serianni] 521—ab
  coronary vasodilators evaluated, [Russek & others] *207
  experimental ethylism, Paris, 663
  ingestion aggravate symptoms of hay fever? 1066
  Propyl: See Isopropyl Alcohol
ALCOHOLISM: See also "Drunkenness" under Medicolegal Abstracts at end of letter M
